>NEC requires connection of the antenna and electrical service grounds.

Hi Richard,
Can you give me the section of the NEC that deals with this? And possibly where to find it on the net? I know this is the way it is done, but I am having to convince an electrican that I'm working with at a new 911 center that we must tie all grounds together.
Thanks,
Dwayne

Try to cut the wire in non resonant lengths, I am getting one for my IC-718 next week and the dealer has a cutting chart.

Jack

> potentially "careless" operator.

This is a difficult problem to analyze. I think the best answer is that in practice, shorting the unused turns has historically been an approach that does a good job of avoiding suckouts. Also, the coupling to the shorted turns is much less than in a power transformer, so the impedance (mostly reactance) that is reflected from the shorted turns is small (but not zero). The geometry of the coil is a factor. I would think that a long solenoid with well-spaced turns would be the best approach. The small reactance that is reflected into the main coil seems to be "well-behaved" and "tends" to be free of suckouts. There are probably some special cases where the shorting approach runs into trouble, but it seems to be the preferred method, and apparently for good reason (it works in most cases).

At high frequency we would be using only a few turns and the many shorted turns would have a very large reactance and would therefore be a small problem.

At low frequency only a couple of turns would be shorted and their coupling to the many used turns would be very small, therefore also not much of a problem.

At midfrequency it could be more difficult to predict.

Dwayne wrote:
"Can you give me the section of the NEC that deals with this?"

If I had a copy of the NEC at hand I would look it up. Perhaps some other reader will supply the chapter and verse. I am relying on memory.

As large transients produce large voltage drops ranging in frequency from d-c to daylight, it is most unlikely that the requirement to interconnect antenna and a-c grounds has been eliminated from the NEC. Even if it were not in the code, you should do it to avoid electrocution and fires on your property.

Best regards, Richard Harrison, KB5WZI

Hi, I have to design an antenna working in the 100-900 MHz band, for receiving digital tv (DVB-T)using a cell. phone. it has to be very small (limited by the size of a cell phone). My main problem is the bandwidth (large lambda values for freq=100MHz), does someone of you know some studies,ideas, or links that can help? Is there a way to get ultra wideband and small dimensions by bending the wires? Thanks!

Please Bill,

Your manners. This is a technical forum. The correct expression
would be
3 weeks +/- 3dB
where weeks are understood to be
the 4th iterative fractal of the second.

Hopefully the 3dB figure does not come from dissipation.
or for the purists:
Hopefully the 3dB figure does come from non-dissipation.

I suppose I should dust off my fractal foolish filosopher tale for the
April first observation. ;->

Richard- you are correct, as usuall, except for one small error, ito
which you were drawn, inadvertently, ny my larger error in time
estimation. I should have said "FOUR WEEKS", with, as you say, the
tolerance factor of +/- x dB. The other error was in the direction of
the iteration- the second is fourth iteration of the week, not the other
way (goes from larger[less detail] to smaller [more detail]).
My error was silly, because this week contained the full moon, with the
additional note that Chips greatest uproars coincide with the full moon.
(This correlation has been noted by several). I should have noted the
current full moon, which was bright enough for me to read my monitor
with no additional illumination.

Yep, I've thought about that. I could add the info for that but have been lazy. I figure if anyone really wants to try to make one of those, they will ask me. Maybe I'll add some info for that and also the data for each type as far as impedance etc. I'm fixing to try the dual 5/8 on 6m I think. I'm presently using a base fed 1/2 wave I've had up a couple of weeks. I'm going to convert it over to a 5/8 with 5/8 radials and see what it will do. The small sizes on 6m will make things pretty easy to work with. So far I plan to use small loading coils for the matching and see how that does. That type of antenna would be matched about the same way as an isopole. Coil + cap if needed. MK

I'm going to put up a 40m vertical with elevated radials. It would be
easy for me to make comparative field strength measurements at different
radial heights while I'm at it. That will give me a spring ham project.
Would a mobile 40m Hamstick be OK for making such measurements?

Yes, he has done modeling on many frequencies. But as far as I know the only measurements he's done are at 8 MHz. The two shouldn't be confused.

> As a bonus, I`ll add his conclusions from the next paragraph:

4565. Re: 160m preamp for RX antenna ??

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-10 22:09:59 UTC
From: Mike Tatum <miket@cybatek.fsnet.co.uk>
Message-ID: <3AAAA63B.8FA09F3B@cybatek.fsnet.co.uk>
Source record: 168836

Hi Group!

Well I'm surprised how many replies I've received, better than the rediculous comments in the
UK amateir radio group :)

Anyways, let me explain a little more!

The antenna is an ex German submarine antenna, designed for use from 30khz to 30mhz.
It consists of 4 2ft long, very heavey, ferrite rods which are arraged in a square, that is two side by side,
on top of the other two which are also side by side.

Around the 4 ferrite rods there is 11 turns of very think wire.
In the middle of these 11 turns I have a single turn of wire which is connected to a length of
RG58 50 ohm coax cable which comes back to the shack.

Across the two ends of the 11 turns of wire I have a 120pf capacitor which resonates the antenna exactly
on 1840khz, presenting around 48 ohms impedance as measured with my MFJ VSWR Analyser.

This antenna is mounted on a small lightweight rotator.
Since the antenna has a very deep null off of either end, approx 60db, it gives me a very steerable
null which I use to null out noise or other stations on 160m.

In this arrangement the antenna is approx. 15db down on my homebrew 160m shuntfed vertical which I use on TX.
I have managed to load a small C&S preamplifier for 160m from Bob, G4VGO and connected it inline with the
submarine antenna.

The subantenna now gives me receive signal strengths that are either the same or better than the vertical
but without the noise, thus making a huge overall improvement!

The reason I have had to go for this type of antenna is because my garden is only 4ft square!

So as you can see, I have very limited space, but am meaeting the challenge of getting a good signal
out and not being an aliigator by improving the receive side as well as the transmit side of things.

I have managed to get across to the USA this winter on 160m which is a first for me, indeed I have a 6hr
QSO with Ralph, N4CQC on 160m, certainly a record for me!

Anyways, I hope you all can now see what I am hoping to achieve and understand where I am coming from
on this.

BTW, I do have some 300m of copper burried under the front and rear gardens which I tuned the vertical
against.

Many thanks to all who have replied, especially those who have toaken the time to reply directly to
me with information on suppliers of preamps.

For reference, the best two suppliers I have found so far are:

http://www.arraysolutions.com/Products/icemain111.htm
http://www.advancedreceiver.com/page12.html

Both of whom I have emailed describing what I am trying to do and looking for confirmation
that their products will suite.

Cheers!

Mike Tatum.

I know it's not clear from the above but the mobile 40m Hamstick is on
the receiving end a few wavelengths away mounted on my truck. It is tied
into a Palomar PFS-1. In other words, would ground wave measurements
yield the desired information?

4567. Isloop antenna in attic - advice??

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-10 22:50:59 UTC
From: "Tom G." <tegwilym@wolfenet.com>
Message-ID: <wdyq6.294$x81.157211677@den-news1.rmi.net>
Source record: 168839

Hello,
I live in a condo/townhouse and just got an Isoloop atenna that I bought from a guy on the internet. My next task is to mount the thing someplace. I do have a patio area next to my unit with a 6 foot tall fence (keeps the neighbors from peeking in!). I'm thinking of 2 options for mounting this thing. 1) On the patio on a short pole around 6 foot tall 2) in my attic which has about 30 inches clearance at the peak (See photo here: http://www.geocities.com/tegwilym/station/setup.html). I figure I could just hang it from one of the beams in the attic someplace away from the other antenna in the picture (this is a QFH antenna for satellite reception). I have had excellent results with the satellite antenna, so I know that RF is getting into the radio ok through the roof. I'm just wondering if the Isoloop would radiate ok from up in the attic also? I have read that it works pretty well without too much TVI, but I'll probably keep it down to about 50 watts at the most - reduce the chance of my neighbors catching me!

Any ideas?

Thanks in advance!

Feel free to mail me direct if you like, I'm already on every spam list anyway so there isn't much good in hiding my email address! :-)

tegwilym@wolfenet.com

Hi Tom,

Try: 1005/freq(MHz)

This is your basic loop diameter equation.

For directive antennas:

Reflector = 1030/f(MHz)
Director = 975/f(MHz)

Source: ARRL antenna book c 1988 pp 5-17, 12-1.

Then I'm probably talking about a small loop.1005/1.8= 558 ft = 186 m.A
little large...

Gary, that's the loop CIRCUMFERENCE... assuming a perfect circle divide it
by PI to get the diameter.

wrote:

>In nut shell quite so.

Not so.

Factually, a preamplifier often is needed on 160 meters with many
receiving antennas. There obviously are many things being ignored in
some of the answers given.

At my location, even arrays of 880 foot long Beverages require
amplification before going to the receivers. My small verticals, and
certainly any small loops (if I had them), would require
amplification.

For a working MEASURED example, noise floor to the NE on an array of
880 foot long Beverages on a quiet winter night, using 3.5 kHz
bandwidth, is -123 dBm with no feedline loss. That's 194 nanovolts (I
have a 75 ohm system) with a very wide 3.5kHz bandwidth.

My FT-1000D barely makes that level with 10 dB internal S/N ratio
preamp on, and that is for wider-than-SSB bandwidths! On CW, forget
it. The receiver sounds stone dead and I would loose many weak signals
that would otherwise be workable without external amplification!

With 350 Hz selectivity, the noise floor is -133 dBm. The weakest
workable signals are at or below that noise floor, so it is very
important to have a bit of headroom. There is no way the FT-1000D, or
any other common receiver, would get into external noise floor
especially if there are any additional significant losses in the
system.

Another factor is AGC. You normally want the receiver into some amount
of AGC on weak signals, so that you are not being "blasted" when a
strong signal appears. If the receiver is somewhat low on IF gain, or
has an AGC system that has a high threshold, you may want some
additional gain.

My array of eight 22 foot tall verticals in a 350 foot diameter
circle, top loaded with wire hats and resonanted with a 33 uH loading
coil and swamped with 70 ohms of loss resistance delivers about the
same signal as the Beverages, and it also requires at least 10 dB of
net gain.

A small loop or array of loops would be even worse.

During times when less gain is needed, you can get away without amplifying signals with SOME receiving arrays, but the general statements offer so far have benn far off base for many situations.

The real answer is "it depends on many things". Site noise, propagated noise, antenna directivity, receiver bandwidth, and antenna efficiency are the major players that spoil cookie-cutter answers.

Many times amplifiers ARE needed.

What you find is true, and what I would suspect with the antenna you
described.

As you have learned from actual experience, you DO need some
amplification despite advice to the contrary.

On small antennas in quiet locations, especially when antennas are
directional wioth close spacing, sometimes a fairly large amount of
gain is required.

I think it would be pretty useful. But I'd still get on the air reports against other dipoles etc. But you can easily do that without even transmitting if you use a switch. I don't think I remember a case where the results were not reciprocal between transmit and receive. But I've got a hunch your "FS" type measurements would give a good idea of the overall efficiency as far as the ground losses at certain heights etc. I oughta put mine back up and let people hear the difference between the two at long distances. One thing, I still insist if you use only 4 radials, you want it at least 30-35 ft high to really play. If you run it lower than that, I'd add more radials to make a fair test. Even at 36 ft, 4 radials is not optimum compared to 120 on the ground. You really need about 8-10 to do this. I came to the conclusion at 36 ft up, 4 radials were appx equal to 50 or 60 on the ground. Still pretty good, but can be improved a bit. So if you drop lower than 30 ft, expect the ground losses to skyrocket as you near the ground. According to the "average textbook" numbers, At 1/8 wl up you will need 60 radials to equal the 120 on the ground. I kinda think your stick will be useful in seeing the effects of this loss as you drop near the ground. I never did any real tests at all when I used mine. I just used it and noted the received results against other antennas with fast antenna switching. My reports back always matched, so transmitting a waste of time for long haul tests I think unless you just want to prove it. MK

Hi Tom!

Thanks for the reply!
I checked the log and found you in there too :)

I have learned a lot from experience!
I remember when I first started working on my short, just 13m, linear loaded vertical for 160m.
I asked a question and got about 100 replies telling me I was wasting my time and here's the maths to prove it!

3 months later I was working US stations on the very same antenna!

I typed the message earlier in a hurry as my portable MAC was about to die due to

lack of battery power, I meant to type 40ft square garden not 4ft square, that indeed would
be challenging :)

Cheers and hope to catch you again on 160m !

73.

So, 289 people realize there's *nothing* worth posting about on
that mailing list.

Sounds about right.

Roy Lewallen, W7EL wrote:
"Yes, he (Al Christman, KB8I) has done modeling on many frequencies. But as far as I knpw the only measurements he`s done are at 8 MHz. The two shouldn`t be confused."

Very true, but physical modeling was practiced long before computers were available for modeling. Scale models are still constructed by some even though those great computer programs are at our service. But the physical model buisness has surely declined in the antenna business thanks to the computer and the bright guys who program them.

All our h-f curtain arrays were first built at about 1% full size for testing at 100x the frequency before being built full-size.

Brown, Lewis, and Epstein when testing at 3 MHz were really doing 1/2 or 1/3 or 1/4-scale modeling because their true interest was mainly in the medium-wave band.

Though Al Christman used 8MHz, it is likely that his test results are applicable to 4 MHz and other frequencies if the right precautions are used.

There likely are some failures in modeling with small-scale antenna models. I never heard of any. I only know of any number of successes.

Best regards, Richard Harrison, KB5WZI

Document this please - for the US. From what I learned, making a patented item for your own use is not violating the patent - as stated by Gary.

I left CB radio 19 years ago when I got my novice ticket. It felt good communicating with people that knew what they were doing and were proud of their accomplishments in getting licensed. Over the past year things have gotten shitty on the bands and operators are stupid. It sounds just like the CB I left 20 years ago except that the rig's readout is showing a ham frequency. To bad there isn't a better radio service I can go to now that the bands are full of idiots. Thanks FCC, Thanks ARRL, I'm back to 11 meters in the middle of a ham band.

I think that you have not been quite honest in witholding some of the data.
My calculations are correct.

> Factually, a preamplifier often is needed on 160 meters with many
> receiving antennas. There obviously are many things being ignored in
> some of the answers given.

Not ignored, but unstated in your original query.
I suspected deliberately as a troll, but it would be unfair of me to sling
such accusations about; though one could hardly be blamed when you see the
amount of set ups that go on in these groups.

> At my location, even arrays of 880 foot long Beverages require
> amplification before going to the receivers. My small verticals, and
> certainly any small loops (if I had them), would require

I thought that you had a 40 foot square yard! ?

> For a working MEASURED example, noise floor to the NE on an array of
> 880 foot long Beverages on a quiet winter night, using 3.5 kHz
> bandwidth, is -123 dBm with no feedline loss. That's 194 nanovolts (I
> have a 75 ohm system) with a very wide 3.5kHz bandwidth.

That is interesting, (obviously not your back yard), and indicates a loss of
approximately 29 dB for that antenna.

-198.6 - (-123) = 75.6
3,500 Hz = 35.4 dB

75.6 - 35.4 = 40.2dB = 10,471°K

Which is approximately in accord with the 9,000,000°K that I proposed for
the Sky Temperature (Tsky) on 160 m during the quite times.

10 log(9,000,00/ 10,500) = 29.3 dB loss.
or 0.1% efficiency whichever way you like to look at it.

> Under such conditions a pre-amplifier is compensating for the AE loss.

Granted, that is correct.
However the S/N ratio is still less than that at the I/P from free space to

the antenna.

Putting 9,000°K directly into a mixer gives

Ts = Ta + Tr
= 9,000 + 2,500 = 11,500°K

S/N in is S/ kBTsky

The signal is 29 dB down too so S/N out is

(eff x S)/(eff x Nsky + Nr)

0.001S/ kB(0.001 x 9,000,000 +2,500)

(Si/Ni)/(So/No) becomes

(eff Tsky + Tr)/eff TSky

(0.001 x 9,000,000 + 2,500)/ (0.001 x 9,000,000)

= 11,500/ 9,000 = 1.28
or approximate 1 dB loss of signal to noise ratio.

Where
Si and Ni are signal and noise in respectively
So and No are signal and noise out respectively

Now with the amplifier gain G;
say for example 30 dB (makes the numbers easier to follow)

S/N = (G eff S)/(G eff (Na + Namp) + Nr)

(Si/Ni)/(So/No)
= (G eff(Tsky + Tamp) +Tr)/ G eff Tsky

= (1,000 x 0.001(9,000,000 + 300) +2,500)/ 1,000 x 0.001x9,000,000

= 9,002,800/ 9,000,000
= 1.0003
or 0.0014 dB

= (1,000 x 0.001x S)/ kB (1,000 x 0.001x(9,000,000 + 300) +2,500)

Thus an amplifier can win you about a dB of signal to noise however you have reduced the dynamic range of the receiver by 30 dB in the example.
It would help if you could provide some AGC to the preamplifier.
If that is not possible it would help to use an amplifier of less gain than my example. We could calculate the break even point, if you want I'll set up the spread sheet to calculate a table for you and you can make your choice to suite your conditions.

If you are working machine modes the fraction of a db signal to noise will be very helpful with rare DX but for 10 dB S/N SSB not much use to you at all.

Presumably on transmit you feed your other antenna which you say is of
comparable gain with 400 kW for full ERP ;)

> My FT-1000D barely makes that level with 10 dB internal S/N ratio
> preamp on, and that is for wider-than-SSB bandwidths! On CW, forget
> it. The receiver sounds stone dead and I would loose many weak signals
> that would otherwise be workable without external amplification!

Of course it sounds stone dead but the S/N ratio of any CW signals that you
receive will be great. once again if you work PSK31 you will not be able to
hear the signals but they are there none the less and if you can tune to
them they will decode without error. HamScope is a great application for
this purpose.

> With 350 Hz selectivity, the noise floor is -133 dBm. The weakest
> workable signals are at or below that noise floor, so it is very
> important to have a bit of headroom.

Let us assume a 3 dB S/N for a CW signal.
(Good Morse ops seem to indicate that they can work at well below that S/N)
lets assume 350 Hz Bandwidth the the threshild in space around the AE is

-198.6 + 10 log 9,000,000 + 10 log 350 + 3
= -198.6 + 69.5 + 25.4 + 3
= -100 dBm Threshold

With an antenna efficiency of -29 dB
you will be able to deliver -129 dBm of signal to the input of the receiver
at a signal to noise ratio of a little under 3 dB
This does not require an amplifier and you do not run into dynamic range
problems in a well designed receiver.

>There is no way the FT-1000D, or
> any other common receiver, would get into external noise floor
> especially if there are any additional significant losses in the
> system.

Would you clarify that please, I don't quite understand what you are saying
here?

> Another factor is AGC. You normally want the receiver into some amount
> of AGC on weak signals, so that you are not being "blasted" when a
> strong signal appears.

The R-5000 is rather good from this point of view; the RF gain can be used
to shut the noise down to the threshold of hearing thus on CW signals the
signal to noise ratio of the tone is almost a quite room effect.

>If the receiver is somewhat low on IF gain, or
> has an AGC system that has a high threshold, you may want some
> additional gain.

I have designed a few sets and I have come to the conclusion that more than
a few dB of gain to cover production spread is a damn nusience. It is prone
to spurious oscillation and intermodulation modulation, clipping and loss of

dynamic range due to saturation of the later stages of the set. Filters
become overloaded and cannot perform correctly. Gain can be a real hazard.

> My array of eight 22 foot tall verticals in a 350 foot diameter

in a 40 foot square back yard?

> circle, top loaded with wire hats and resonanted with a 33 uH loading
> coil and swamped with 70 ohms of loss resistance delivers about the
> same signal as the Beverages, and it also requires at least 10 dB of
> net gain.

I suppose that if you are that serious to construct such an antenna, it
would pay you to build an efficient AE that can also be used for
transmitting and have a respectable efficiency.

> A small loop or array of loops would be even worse.

Surely this would be a compromise AE forced upon the Ham by space or
p[lanning restrictions. Top band is definitely for the landed rich, (I won't
say gentry, there aren't many gents about these days :)

> During times when less gain is needed, you can get away without
> amplifying signals with SOME receiving arrays, but the general
> statements offer so far have benn far off base for many situations.

I think that is down to the fact that you witheld some of the information
thus wasting peoples time in giving a difinative answer when a single line
would have been sufficient to dismiss your query, (I'll know next time).

> The real answer is "it depends on many things". Site noise, propagated
> noise, antenna directivity, receiver bandwidth, and antenna efficiency
> are the major players that spoil cookie-cutter answers.

I considered all of the data required to cover a normal situation the fact
that you had undeclared restrictions was unhelpful.

> Many times amplifiers ARE needed.

I'm afraid that you have demonstrated a straw man.

And it looks very much like a scarecrow from where I'm standing :)

Never mind; that's what this hobby seems to be all about.

Thanks Richard, second attempt worked OK
$95 is a bit more than I can afford so I'll see if I can get the book
through the library.

The interesting comment in the summary for the book about his company discouraging publication I can confirm.
When I worked at "The Gram" I was actually in the lab that Blumlein had been using just before his tragic death and one of the people that had known him personally was still working there. I did have a few conversations with him about Blumlein, but never managed to get anything on paper about this unrecognised giant.

Bill:

I concur, to the best of my knowledge, in the USA, it is perfectly legal to build personal use instances of any US patent. You just can't use these personal renditions for any commercial purpose. Building instances of patented inventions for personal use and study is completely legal.

There are two main parts to every patent, the first is the tutorial or "teaching" part, and the second is the listing of the "claims" of the invention.

As explained to me by several patent attorneys and patent agents over the years, it is my understanding that the whole reason for having the tutorial or teaching part of the patent is to teach others how to build personal use instances of the invention. In fact, I have been told that, if it can be proved that the information in a patent document is not sufficient to produce a personal use working instance of the invention, the patent can be declared invalid.

The whole structure of the US, and most English common law style patent systems, is set up so that, in return for teaching the rest of the populace how to build the invention and letting them do so for personal purposes, the government grants the inventor an [17 year?] exclusive right period to its' commercial exploitation. At the end of the [17 year>] exclusive rights period, anyone can take the patent and the "teaching" and exploit it for either commercial or personal purposes. Until the exclusive right period has passed, only personal use is allowed.

Without the "teaching" part of a patent, the claims alone would be sufficient to document and protect the invention. And so... I presume that's why the patent law requires the inventor to "teach" in the body of the patent before the "claims" are listed so that anyone can build an instance of the patent for personal use. Just do it!

Claims are not required to "teach" but simply to exactly document the salient recognizable characteristics of the "invention" so that commercial violations can be tested for infringement in a court of law.

I don't believe that any ham is forbidden from building or having built for him or her at no charge, a "patented" antenna for his or her own use. Just don't try selling or giving away those personal use implemenations of the patented antenna within the exclusive rights period of the inventor.

And so I believe that hams can build so-called patented fractal antennas for their personal use without fear of reprisal from the "inventor":. All that being said, if one reads the patent claims of the recent patent assigned to Fractal Antenna Systems closely, I believe that the reader will come to the

conclusion that the claims are narrowly stated, and very weak, and do not have the generality of a "concept" patent. Those claims for the fractal antenna seem, at least to me, to constitute what is usually described as a narrow or specific "design" patent and not a "concept" patent. Sort of like a copyright, the specific detailed designs of particular "bent wire" antennas are claimed, but not the general techniques.

So, I say... have at it... build patented fractals for personal use and enjoy!

And... don't be afraid to create and try to patent your own bent wire antennas, for, as far as I know, there are no generic patents that prevent the development of bent wire antennas no matter how the places in the wire and the directions of the bends are arrived at. I like Cecil's Dead Cat technique myself.

Please be advised that I am not an attorney and that the above information and advice is passed on in the interest of sharing my beliefs with my fellow amateur radio hobbyists. Caveat Emptor.

Are there any patent agents or lawyers out there reading this NG posting who can confirm my understanding of these matters?

Simple enough to check.

That array, after feedline losses are deducted, is typically slightly
less than 20 dB down from a 200 foot tall single element vertical with
100 200 foot long radials and a vacuum variable and large edge wound

inductor for matching, when signal levels from distant stations in the
direction where the Beverages point are compared.

It might be as much lower as 12-20 dB (QSB, sorry), but it very
obviously is much less than 29 dB down.

You are pulling numbers from the thin air instead of staying with a working example. That's often a problem when people ask a simple question, and get an answer from a textbook.

1.) The FT-1000D, which has a fairly good receiver by amateur standards, has about 10dB S/N with a .2 uV input signal and 2.5 KHz selectivity. That's a NF of 20 dB, or a temperature of almost 29,000 k.

2.) The sky-noise you are using is not accurate at every location, every season, and every time of day. It is also most likely for a non-directional antenna.

Ignoring the above is NOT a good idea, when answering a question.

>It would help if you could provide some AGC to the preamplifier.
>If that is not possible it would help to use an amplifier of less gain than
>my example. We could calculate the break even point, if you want I'll set up

>to suite your conditions.

No, that is NOT true at all. AGC to the preamplifier would only work when the desired signal was into the AGC response. As a rule, overload and IMD comes from signals outside the passband of the receiver.

AGC would have no effect on the systems IMD performance on weak signals...where it is most problematic.

More important than this, you are dictating my system works differently than it actually does.

>If you are working machine modes the fraction of a db signal to noise will

Nonsense.

PSK is not as effective as the human ear on CW (assuming you know
morse code, and have normal CW skills) for digging signals out of the
noise.

Readability is far better on CW than on PSK, when all things (gain,
receiver bandwidth) are equal.

It's better get back to consider there things by fact, not hearsay.

Sure you did. The fact that you posted this message to nine newsgroups, used a fake identification, and made numerious false statements about ham radio, clearly shows this as an attempt to stir up trouble instead of voicing an honest complaint. If you want to stir up trouble, try not being so transparent next time. Until then, you rate less than a one on the old troll-o-meter.

Hi hall

I have found a coupler antenna type CU-421/SRA-15.
It is in very good conditions but i have not specifications for use.

Anyone know it ? Can help me ?

Thanks

Agreed. So the only value of a patent to non-lawyers lies in its properties as an advertisement of the novelty of what has been patented.

And for last 12 months or so, one particular patent has made a name for itself on this newsgroup as the greatest timewaster ever.

You need to get your meter checked, TR. This message was way too transparent to rate a ten. It also lacked the style and sophistication to be a highly rated troll. My meter still shows it as less than a one (and its a generious meter).

From the U.S. Patent and Trademark Office FAQ
http://www.uspto.gov/web/offices/pac/doc/general/whatis.htm:

"The right conferred by the patent grant is, in the language of the statute and of the grant itself, 'the right to exclude others from making, using, offering for sale, or selling' the invention in the United States or 'importing' the invention into the United States. What is granted is not the right to make, use, offer for sale, sell or import, but the right to exclude others from making, using, offering for sale, selling or importing the invention."

There's a lot of good and accurate information about patents at the USPTO site.

We measure ground wave strength for our 75m mobile antenna shootouts.
Why wouldn't those techniques work for vertical antennas? Seems
stronger ground waves would correspond to lower angles of radiation.

There was a story on one of the 60 minutes type programs
recently that drug companies are able to patent genes. The
story used as an example the patenting of a gene that seems
to prevent aids.

So if you can't make patented items, who's going to tell the
poor people whose genes have to be ripped out?

:-)

>Jim Pennino

Hi Jim,

I heard the same thing from K1BQT, and figured out why he thought it
was true. There certainly is no technical reason why PSK would be more
reliable than CW...as a matter of fact the opposite is true.

Because PSK looks for a carrier drop and an abrupt reversal in
phase...it has to be above the noise to be decoded.

CW, on the other hand, can easily be copied with a zero dB S/N ratio.
Many or most skilled CW people can copy CW with negative S/N ratios.

The reason the myth that PSK allows us to work stations we "can't
hear" exists is because most PSK ops use a wide bandwidth on the
receiver, and move all the selectivity to the computer.

By ear they are listening to a bandwidth of maybe 3 kHz, while the
audio filter is set at perhaps 70 Hz. In this case the computer sees a
16 dB reduction in broadband noise compared to what the "ear" hears.

If we use 250Hz selectivity on the receiver, we'll find we can plainly
copy CW signals at level that produce very poor print on PSK.

Now I certainly agree that there might be a "woooden eared" CW op who
might not copy signals that a PSK system will decode, but that would
be the exception rather than the rule.

Because I can copy CW signals with a negative S/N ratio, as can many
other CW ops can, the difference to me is startling. It has to be an
absolutely solid CW signal to get any print at all on the guy on PSK.

Try setting your bandwidth to 250 Hz, and see if you don't notice the
"PSK advantage" going away. I can work DX stations perfectly solid on
CW that I have no hope of decoding on PSK.

PSK not only requires higher S/N ratio to decode, it also requires
much higher average power than CW to deliver the same information.
It also has exceptionally poor dynamic range. That's why PSK operators
whine constantly about QRO operators.

Hello everyone.
Julian KB9YXM
I have 2 questions for you old timers around.
The first is a 6 meter yagi that can be used as a portable yagi for operation out and about in the forest and mountains.
So my question is, "Can anyone tell me how to build a 6 meter yagi that would fit the bill?"
My second question is, I have a Yaesu ATAS-100 antenna that I would like to use as a portable Base Station antenna again out in teh forrest or it the mountains. Can anyone here help me to build a a ground plane kit that would work well out in the bush. Drawings of some sort, I could fugure out the numbers myself but I need the basic idea and a drawing of some sort would be great.
Thanks everyone and 73's
Julian White

Hello Rick:

Thanks for that information on AOL mail account "ownership:" Heh, heh.

Seems sort of like a ham radio "pirate". The call you hear on the air may not be the "real McCoy" it could be someone else using ventriloqy. Could it be that Phil is really the voice of Edgar Bergen or Senor Wencelas?

BTW... what is AOL? Being an "old time" Internaut, and active USENET NG user since the days of UUCP ubiquity on PDP-11 dial up networking, I'm not familiar with AOL... is that one of those On Line Services like CompuServ? [I hope Steve Case is lurking, I can hear him choking now!]

I suppose that, having been around the Internet to experience UUCP dial up networking, is sort of like having been around ham radio when "Spark" was in use.

I really liked your latest article in QST, keep it up, we need more...

Best,

-Peter K1PO

Nothing specific, only in the specs does it say will tune 3.5-54 mhz with an antenna longer than 23 feet...that's it, couple of drawings showing a whip and a long wire and formula to calculate undesirable lengths...I mistakenly figured I might find someone here who had actually used one of these in the fashion I'm considering- you know a helpful tip or two !!
Oh well...

No. You may make an absolutely identical item for your own use, so long as you do not reverse-engineer an original to do so, use original design documentation, or ever transfer it or offer to transfer it to another person without getting a license from the rights holder.

Or, in other words, if you come up with the same idea, you can only get sued if you try to profict from it.

This is from U.S.C. Title 35 Chapter 28 Section 271:

(a) Except as otherwise provided in this title, whoever without authority
makes, uses, offers to sell, or sells any patented invention, within the
United States or imports into the United States any patented invention
during the term of the patent therefor, infringes the patent.

There are exceptions in the title, but there is no exception for personal use.

> There's a lot of good and accurate information about patents at the
> USPTO site.

Case law goes way beyond the FAQ, which, as written, would give the
rights holder the legal right to prohibit specific individuals the use
of an item purchased through the authorized channel.

The FAQ would also give the rights holder the power to prevent sales of
the item used, and you KNOW that there are plenty of companies who would
use that power if they had it.

Patent and copyright laws are significantly different. A copyright DOES
grant those powers (ask anyone who has bought a Motorola RSS), but a
patent does NOT.

Take 3 noncunductive poles. Tie them hear the top, then lift them up
into a tripod (teepee supports). Just drop the line across the fork and
you're in business.

try posting this at http://www.eham.net in their "Ask the Experts"
section. I think ICOM needs to post their manuals in .pdf format like
Kenwood. Not that this would have helped in this instance but a least
you would have been aware of the unanswered question before buying. I
noticed that especially the ICOM antenna tuners have very limited
information available on the web.

The U.S. patent law can be found at

http://www4.law.cornell.edu/uscode/35/

Since it is hard to prove a negative I would simply challenge you to
find something in the law which supports your assertion. What Roy said
matches what the law says pretty accurately. I don't think there
is anything in the law which matches what you said.

4629. CATV coax cable SHIELDING as an antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-11 18:30:47 UTC
From: Keith Wood <kw@bctv.com>
Message-ID: <3AABC457.B4DE45FA@bctv.com>
Source record: 168801

I'm in an condo, can't put up a wire, but there IS an unused CATV lead-in (75-ohm coax) running right to the room where my HF rig will be.

Has anyone ever tried and had success with using the cable shielding as an antenna in such a case? It's disconnected at the pole, runs 25 - 30 feet (NW - SE, dropping 10 feet) to the corner of the house, then 14 feet along the eaves (N-S), then 9 feet vertical drop to the feed through.

4631. Re: Wet Ladder Line

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-11 18:39:49 UTC
From: Bill Ogden <wogden@attglobal.net>
Message-ID: <3aabb93a_4@news1.prserv.net>
Source record: 168792

I wish to thank everyone who commented on my question about wet ladder line. My conclusions (based on group replies and private replies) are:

1. In theory, the wet line should not make much difference. (Exception: Roy's comments go against this conclusion.)

2. In practice, there can be a substantial problem -- especially on the "higher" bands (which I take to mean frequencies above 20 m).

My current use is modest -- involving a 45' dipole, up only 20', with about 110' of feed line. I plan to put up a full-wave (on 20 m) loop, with relays to open the "top" of the diamond loop, and use it for 30-10 meters. The top of the loop will be about 66' high, with about 150' of feed line, and the whole thing will be difficult to take down for changes after it is installed. I am beginning to think I should go with open line instead of ladder line. I have never worked with open line, and it looks like handling it (standoffs, feeding it through a wall, running along a basement ceiling, etc) could be a bit messy. Perhaps it is because we have had an unusually wet winter, but I am disappointed in the ladder line. Even heavy dew seems to affect it. (Several people pointed out that the high impedance of my current antenna, on most bands, contributes to the problem --- but my proposed loop has the same exposure.)

Hi Gary,

Perhaps a slight bit of adjustment of perspective will help.
Copyright and Patent law, philosophically in a Capitalist state, is
aimed at protecting the owner from a loss of revenue.

Then you need to get a new meter. His meter detected a troll, period. Don't you think that something as dumb as a meter would register a 10 on, as you say, something as transparent as "ARRL's" post? Also, try using your spell check. When a person flames another but in the process misspells a simple word as "generous", they tend to lose all credibility.

Hi John,

There's a glut of military surplus field masts on the market. They
come kitted up ready to deploy (no instructions provided) a 30 to 40
foot tall mast guyed at two or three levels. You get the mast as
stackable 5 foot tubes (heavy wall), guy plates, guy lines, stakes,
and sledge hammer for stakes (no instructions provided).

As a kit, not much bigger than my old seabag (same color, same
material). $90 and 40 footer was mine.

Mobile I used an SGC-230 and a 12ft whip to cover 20m-10m and
even 40m in a pinch. 12ft is 1/2WL on 39MHz so I didn't have
to worry about that. Just avoid any length that is 1/2WL on
any bands on which you want to operate.

4636. 102" Whip vs. Bug Catcher - some measurements

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-11 19:13:47 UTC
From: Doug Hall <k4dsp@pobox.com>
Message-ID: <1uhnatopo6edlou2l60oo5ophp4ft2svbo@4ax.com>
Source record: 168811

Hi All,
For those who contemplate HF mobile at some point I thought you'd be interested in this comparison between a couple of different HF mobile antenna systems.
I compared a Radio Shack 102" stainless steel whip ($14.99) and Icom AH-4 autotuner ($309.95) to a center loaded antenna called the "Carolina Bug Katcher" ($99.95) from Lakeview Antennas (www.hamstick.com) Since the whip is only resonant on (or near) 10m I used the Icom AH-4 tuner with the whip. The bugcatcher, which covers 40-10m, doesn't need a tuner, but I left the tuner in line anyway just to keep the system the same all the way back to the antenna mount.
The purpose of the exercise was to see if the whip and tuner would be an acceptable alternative to the bug catcher. The whip/tuner is nice because I can change bands without stopping the car and changing coil taps. This is attractive when it's cold/rainy/dark. Also, the whip isn't as "ugly" as the bugcatcher, or at least that's what my daughter says. But beauty is in the eye of the beholder.
The test setup was as follows: The radio was an Icom 706Mk2G mounted in my car. The antenna mount is on the rear bumper. Each antenna was tested on the same mount, same feedline, etc. In other words, the system was the same except for the actual radiator being compared. I parked the car in a large open area away from other vehicles, and used a COM-120B service monitor in the lab at my office to monitor the field strength. I then transmitted a carrier on each band with each antenna with the radio set to the same power level. A friend of mine recorded the field strength readings on the spectrum display on the service monitor in the lab. Here are the results:

Band	Bugcatcher	Whip	Winner
40m	-62dBm	-76dBm	Bugcatcher, by 14dB
30m	-64dBm	-76dBm	Bugcatcher, by 12dB
20m	-44dBm	-52dBm	Bugcatcher, by 8dB
17m	-66dBm	-74dBm	Bugcatcher, by 8dB
15m	-59dBm	-69dBm	Bugcatcher, by 10dB
12m	-50dBm	-58dBm	Bugcatcher, by 8dB
10m	-58dBm	-56dBm	Whip/tuner, by 2dB
6m	-65dBm	-64dBm	Whip/tuner, by 1dB

Note: The readings are likely subject to an error or a dB or two. But the data tells a pretty convincing story, and should probably come as no surprise. Base loading just can't compete with center loading when it comes to efficiency.
Using 100w into the whip on 40 and 30m (the bands I use most) would be like running only 4 or 5 watts with the bugcatcher. Or put another

way, I'd have to run over 2500w on the whip to match the bugcatcher's 100w signal. It's not until you get to 10m and 6m (where the whip is no longer electrically "short") that the performance is similar. And of course, the gain of the bugcatcher is there on receive as well. You can't work what you can't hear.
Your mileage may vary. Comments are welcome. The usual disclaimer applies - I have no association with any of the companies listed here except as a customer. Also, the Carolina Bug Katcher is no longer available according to Lakeview's web page. But a similar antenna is available from Henry Allen K5BUG at www.texasbugcatcher.com

I use 2x4s in a 4x4 configuration for the bottom sections and then
fiberglas pipe for the upper sections.

Well, I'd just string out the longest piece of wire possible, apply that formula
to it to make sure it's not an undesirable length, and then see which bands it
loads up on. Icom's absence of any real recommendations may be because one
simply needs to experiment with this device. (I have an mfj tuner that came with
a similar lack of instructions, but I guess you expect that from mfj :-(

I wouldn't call an antenna tuner at the base equal to "base loading".
Base loading would be putting the loading coil at the bottom of the
antenna which is better performance than an antenna tuner because
the coil radiates coherently with the antenna. Real base loading is
"only" 3-4 dB down from center loading.

If that is the case, how is it that Eznec radiation patterns show
maximum radiation from a short grounded vertical occurs at a
considerable +ve elevation angle - simultaneously with zero
radiation at zero angle along the ground ?

Reg.

EZNEC doesn't display ground wave signals by default, Reg.
My theory is that the lower the angle of radiation, the
more powerful the ground wave is in the vicinity of a few
wavelengths away from the vertical antenna. The question
I have is would raising a ground plane cause the measured
RF to miss the target antenna which remains at ground level?

4647. PVC vs CPVC K factor

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-11 20:39:49 UTC
From: xxxpjock@gte.net
Message-ID: <poRq6.2835$oj3.796769@dfiatx1-snr1.gtei.net>
Source record: 168720

Does anyone have any information comparing the "K factor" of PVC versus CPVC pipe? I have seen some very interesting antennae construction pages on the net using PVC pipe as an enclosure, but I thought CPVC might last longer in sunlight. I understand UV destroys PVC after a time, while CPVC is more resistant to it.

Thanks and 73,

Phil - N4GWV - pjock (at) gte.net {note clever anti-spam ploy...}

4648. Re: Wet Ladder Line

Newsgroup: rec.radio.amateur.antenna

Source record: 168722

OK Roy, I change my-non quantitative description of clean water
from "low loss" to "not low loss".

You have obtained from that handy data source of yours a
loss-factor of 0.04 at 1 MHz. This corresponds in a capacitor to a
Q of 25. If such a figure is due to molecular resonance then it
almost certain the loss-factor varies like a yo-yo over the
frequency spectrum. It may be zero at some HF frequencies. Any more
info ?

Your measured values indicate maximum loss did not occur at maximum
amount of water but at some intermediate value. This suggests some
other material or mechanism is involved. Or was it, perhaps, a
measuring error ?

Someone else remarked pH of rainwater is seldom 7. I undersatand
it is always acidic - lightning produces HNO3 = nitric acid.

I'd be grateful if someone could let me have the bare HF essentials
of Beldon 8230: Zo, velocity factor, conductor diameter, spacing
between conductor centres, and attenuation dB per 100 feet (or 30
metres) at some frequency. I've never heard of it.

Thanks.

Reg

Hello there John ... Tom KI3R Port Vue Pa. I ran an inverted vee for a number of years on 40 using metal TV mast. Now I know some guys will say that the metal and its inherent length will cause difficulties. I had none. However I did turn down a dowel rod to fit inside the last section and used a HyGain balun there. Again if there were problems my signal or neighbors didn't let me know. Just be sure to guy obviously ..I used 2 at 90 degrees to the wires ... rayon line if I remember.

God Bless 73 Tom

One can sympathise that anyone that has invested time and effort into
producing some novel device is morally entitled to the benefits of that
device.

Of course patent law has been used in a criminal fashion on more than one
occasion where patent has been taken out on the work of another.
One famous example being penicillin.

Actually a patent only protects the originator of a novel device if the
patentee has the resource to detect and prosecute at his/her own expense any
infringement of that patent.
In the long run when it comes to Law the process is determined by who has
the deepest pockets not the moral right.

A patent in principle is little different to mailing yourself a description
or working model of the novel device in order to demonstrate to a court that
you have the prior example or specification for the item in dispute by
virtue of the time stamp on the sealed envelope.

The fact that you have lodged a patent with the patent office merely uses
that office as a recognised depository of the chronological inception of the
novel device.

The patent office do not police or prosecute on behalf of the patentee.
So what DO you get for your money?

Actually, Tom, I have spent hundreds of hours doing disaster
communications. But I never demanded that people in Nebraska pay for my
then-insistence on living in the Fire Ring. Eventually, I moved.

It's not the government's money, it's my KIDS' money. Why do you feel
that you have a right to take it, because you choose to live where you
do?

How about some compassion for my kids? You want to take the food out of
their mouths.

Buy your own insurance. Fix your own house. Or move.

Don't demand MY money to cover for YOUR choices.

When I do legal research, I am paid for my work. However, I would turn
this around, and invite you to show me ANY case under the current US
patent law where a private person lost a suit over private,
noncommercial manufacture and use of a patented construct.

Just a little. From the same source, the dissipation factor is 0.005 at 100 MHz, 0.157 at 3 GHz, and 0.265 at 25 GHz, not of much use in seeing what happens over the HF range. I think the first resonance occurs well above HF, but I really don't know for sure.

> Your measured values indicate maximum loss did not occur at maximum
> amount of water but at some intermediate value. This suggests some
> other material or mechanism is involved. Or was it, perhaps, a
> measuring error ?

Although measurement error is always a possibility, the methodology was so simple that it's unlikely. I felt then, and do now, that the cause is likely due to the cleanliness of the water. The line had been out in dry weather, subject to dust, for a couple of weeks before it first rained. So the line surely had a coating of dust on it. After it rained awhile, it's reasonable to assume that at least some of the dust was washed away. Dusty water is a whole lot more conductive than pure water, so I'd expect the loss to be correspondingly greater.

The _CRC Handbook of Chemistry and Physics_ shows some interesting figures for the DC conductivity of water with varying amounts of ordinary salt dissoved in it. The conductivity of pure water is given as 0.0 mmho/cm. With enough salt to depress the freezing point just 0.037 degrees C (0.01 g-mol/l NaCl), the conductivity is 1.0 mmho/cm (0.1 S/m). At 1 degree freezing point depression (about 0.3 g-mol/l), the conductivity is 26 mmho/cm (0.26 S/m). Compare this to "average" soil at 0.005 S/m, and it becomes obvious that even a teeny tiny amount of dissolved salt makes water quite conductive indeed. Coupled with its high dielectric constant, you have a bad combination.

Help!

I have a Wilson WR-1000 Rotor and control that have never been used.
Unfortunately,
I need a 10 pin connector to fit the old Wilson WR-1000 rotor and the
documentation/manual for the rotor and control box.

"I think" I have a connector, or at least I had one, but can not find it.
I never did have a manual.

I'd greatly appreciate any help.

If any one responds, please copy me via e-mail as I don't always get to see
replies on the newsgroups.

Thanks,

Brian: 23 feet is the minimum length of wire for you coupler. This length is at the "bottom" of one of "non-resonant" windows. This "window" is the first one of significant size that will produce a decent signal. The window is 23 to 32 feet, with 28 feet about the center of this window. Here are some more "center" window lengths: 40, 58, 76, 95, 109, and 145 feet. Generally, you can go about 4 or 5 feet either way of center and be OK. Use the formula 300/freq mhz x .5 to aviod multiples of half waves on any given freq. Using the formula and the above lengths, I don't think you will come up with any of the above lengths. I like the shorter 4 as they are easier to work with. Try a 40 foot (or bigger) loop with your coupler. Try the 76 foot length in an inverted L configuration. I like using insulated 12 gauge stranded wire or Flexweave wire because it is a lot easier to work with vs the hard drawn bare stranded 14 ga "antenna" wire as this will tend to kink and bind and is hard to wind up for portable use. The "quality and size" of your ground and/or counterpoise DOES matter with this system. As a rule of thumb, keep your counterpoise about 10% longer than the antenna wire, i.e., 58 foot antenna wire, use at least 64 feet counterpoise radials. 4 minumum. 8 works real good. 12 is real nice. More is overkill for this system, in my opinion. Keep them fanned under the antenna wire. Have fun matching stuff and making new "things" talk.

G'day, as for the inverted "V" I have a B & W end fed wire antenna in a inverted "V" configuration and it works great the centre is about 50 feet high and both ends about 12 feet off the ground.

I work DX all over the world and have good coverage on 80 meters 300 to 600 miles at least running only 100 watts..

Hi Tom,

I'd buy the bandwidth arguement except for one thing. I normally use the CW filter on weak signals to keep the locals from AGCing the weak ones out of existance and I still can't hear the PSK signal, oh maybe a little now and then, just enough to tell there is something more than noise there. But enough to be copyable CW, not a chance.

Now, if I had an outboard DSP audio filter with all the tricks built into it that the PSK program has, I just might be able to hear it, but I don't. So given a stock tranceiver and a PSK program, I can work PSK that I can't hear.

I have no idea where the poor dynamic range comment comes from other than perhaps the problem of strong signals AGCing out the weak ones, but you have that problem with all modes. It just gets focus on PSK since most everyone runs 30 to 40 Watts and some clown running 200W REALLY stands out.

I have seen differences in the abilities of PSK programs; some are noticably better than others. Perhaps you should try a different one. Hamscope for example, seems to do everything so so and apears to be quit sensitive to QRM. WinWarbler only does BPSK and QPSK but with some playing with the FFT parameters does it very well.

I don't think so. Also the small changes in the elevation pattern will
be hard to detect I think. I think you will see more FS difference due
to ground loss changes than elevation pattern change. MK

I made a simple mounting bracket for my ATAS out of 2" aluminum "L" stock, and a 2" SO-239 barrel connector. I use u-bolts to attach it at the top of a 30' push up mast, and for a counterpoise I cut pieces of regular hookup wire at 1/4 wave lengths for each of the bands. I attach one end of these counterpoise wires to the "L' bracket and a small weight to the other ends and just let them hang down.

It works great for me, the ATAS tunes fine on all bands and I get good signal reports both stateside and overseas.

Doug,

Your test results were consistent with my own experience. No matter what, anything other than a Hi Q, resonant antenna is a compromise and, generally, will not work as well as the resonant antenna. I was using center-loaded antennas in the late '60s, and, since I love to experiment with mobile antennas, I did lots of comparisons. In every case, and accounting for certain anomolies, the center loaded antenna wins every time.

As you say, "your mileage may vary", and, certainly, one must take into account one's spouse's feelings about big, "ugly" antennas on the family car. Sometimes, one just cannot have a huge antenna and must do the best they can with what they are able to use.

I build screwdriver antennas, and one of the things I did with mine was to get away from PVC and "skinny" little windings. My own screwdriver is a 3" version and is comparable to the old Henry Allen #66 Bugcatcher coil. It has excellent performance.

I hear lots of fellows bragging about how "well" they do with hamsticks. Not criticizing, of course (to each his own), but I find them to be the WORST performing antennas around. Just MHO, but to my mind, it does not make sense to buy a $1000 radio and hamper it with a $20 antenna. That antenna hanging onto the bumper can make or break your station, and I want the maximum from my mobile.

Thanks for sharing your test results with us.

4666. Re: CATV coax cable SHIELDING as an antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-12 02:20:03 UTC
From: Bob Camp <bob@cq.nu>
Message-ID: <nnWq6.146014$Vj5.21874927@news02.optonline.net>
Source record: 168742

Keith,

One risk is that it is still grounded at the pole. If it is then you will be loading into the CATV system ground. I suspect that your cable company will be less than happy about the results.

The other risk is that it is not grounded at the pole, but is still pretty darn close to the break out box. In this case you probably will have a lot of RF within a few inches of the CATV stuff. Again highly likely to make the cable guy a bit bothered.

As a receive antenna it should be pretty darn good at picking up power line noise .....

Did I mention what happens when lightning hits the power / cable lines .....

All that said - yes you can load it up with a good tuner and it will get out better than a lot of antennas.

I am taking down a TH6-DXX and putting up a vertical due to space limitation. Need to handle 1000 watts and work 10-15-20-40-80 meters. Been looking at many manufacturers but which is the best? Anybody have input ?

I don't know what you mean by "lower angles of radiation", unless you mean the elevation angle at which the sky wave is maximum. Broadcasters go to great pains to minimize the sky wave while maximizing the ground wave, illustrating that you can't necessarily correlate the two.

The ground wave and sky wave do change in proportion, of course, if you don't make any change in the antenna except its efficiency. Neither the ground wave nor the sky wave radiation pattern changes shape in that case.

If you're talking about using a hamstick for measuring the field from another vertical, it should be fine, as long as you're careful to eliminate any significant response to horizontally polarized fields. If you use it as the test antenna with various ground systems, you'll have some information about how a hamstick does under those conditions, which would be interesting. However, it might not be easy to extrapolate the results to what you'd get with a full sized vertical.

Sorry, I answered the first one before I read this. When you elevate the radials, you make very little change in the radiation pattern, so I believe you could use ground wave measurements to measure the relative efficiency of various ground systems. I'd recommend getting far enough away from the test antenna that its height is negligible relative to the distance.

Listen buttwad, you were the one that said all antennas are fractal. You and your lawyers can all go get to know each other in the biblical sense.

Fred W4JLE
3/11/01

PRIVATE AND CONFIDENTIAL

On 3/11/01, Fred Hambrecht posted the following public statement on rec.radio.amateur.antenna:

<< I hope he doesn't find out about my sales of 11 meter fractal antennas. Seems the CBers love them and I haven't been able to build them fast enough. I spec them at 27 dB gain and simply point the prospective users to the freaktenna web site. They come away so confused that any gain figure seems supported.>>

Mr. Hambrecht:

I am writing to request that you provide details regarding the sales of the fractal element antennas you have publicly discussed. It is likely that your sale of said products is in patent violation with respect to the patents assigned to Fractal Antenna Systems,Inc. You may wish to search on the www.uspto.gov site to get more information about these issued patents.

In addition, Fractal Antenna Systems, Inc. has pending patents that also are quite likely to be infringed upon issuance by these sales.

If these antenna products consist or comprise parts which are described by our extant patent claims, you are requested to cease and desist in their sale effective immediately. I urge you to review your sale of these products with your attorney.

Thank you for your attention in this matter.

Cordially,

Nathan Cohen, Ph.D.
CTO
Fractal Antenna Systems, Inc.

>you have that problem with all modes. It just gets focus on PSK since
>most everyone runs 30 to 40 Watts and some clown running 200W REALLY
>stands out.

We sure don't have an AGC problem with all modes! Virtually all other
modes match the BW of the receiver to the BW of the signal. Receiving
a 70 Hz wide signal on a 500 to 3000Hz wide receiver is just asking
for problems with off-channel signals blocking the receiver.

I don't operate CW with a 5 kHz filter, and I don't operate SSB with a
40 kHz wide filter. If I did, my life would be spent whining about
other people being too strong.

With propagation making far more than 50 dB difference and the
additional difference between antennas, I don't know how you can tell
a 200 watt signal from a 35 watt signal. That's only about 7 dB
difference Jim, not 50 dB.

While the use of a nbarrow CW filter helps the receiver problemss, PSK
ops still have tendency to hunker down in clusters a few hundred Hz
apart. Not only that, since the PSK tone is dumped into the audio
chain of a SSB transmitter, all sorts of problems can be created.

There is hum and noise from ground loops, harmonic distortion (that
does not show up on your IMD display), and even less than perfect
carrier and sideband suppression in a few rigs.

All of this stuff adds up to poor performance when strong signals are
mixed with weaker ones.

>I have seen differences in the abilities of PSK programs; some are
>noticably better than others. Perhaps you should try a different one.

I have the program in my DX4WIN software, and Digipan. I can send CW much faster than I can type, so I really don't operate PSK much. If I want to type, I can get on Internet and run all the power I want.

30" I thought I had it rough!! Good job on scarfing up a Isoloop. I would
put in your attic if it would be reasonably clear (better than 4 feet) of
any large metal objects (furnace flue, power wiring ect.)
Also the weakness of the Isoloop was poor tolerance to weather (plastic case
would crack and break down and no parts to be found). 50 watts might be too
much on some bands (10 & 15m possibly) for good neighbor relations, take
advantage of the relativity good efficiency on the upper bands and go easy
with it.
Good Luck

==========
If EZNEC doesn't display ground wave signals by default then it
doesn't display low angle stuff with any degree of accurately
either. Otherwise, at what elevation angle does accuracy kick in ?

But I don't think any severe measurement problems will occur by
elevating the radial system of a short antenna a short distance
above the ground provided the transmitting and receiving antennas
are 8 or 10 wavelengths apart, ie., not within each other's near
fields.

The radiation patterns along the ground and at very low elevation
angles of 1/4-wave and 1/40-wave ground-mounted verticals are not
very different from each other. But EZNEC won't show it.

I suppose if the discrepancy was known then it could be corrected
by tilting the elevated transmitting antenna slightly in the
direction of the receiver. Intuitively, it won't matter very much
anyway. Other factors will produce greater discrepancies. For
example, raising height only a small amount from the ground will
greatly change ground induced loss. It will also severely detune
the system.

We are considering measuring techniques and accuracy. So the words
"greatly" and "severely" are relative. Over a practical skywave
path hardly any difference would be detected by a small change in
height of radials once they are above the ground.

==========
Sorry Cecil, must disagree.

There is no difference whatsoever between a loading coil at the bottom of the antenna and a coil in the tuner immediately adjacent to the base of the antenna. A coil in an HF antenna conductor radiates no more than the length of the conductor the coil has replaced.

This is because the currents flowing horizontally in the coil turns flow in opposite directions on opposite sides of the coil and, being relatively close together, cancel out. This neat little analysis falls down at VHF where the coil diameter becomes a large fraction of a wavelength. Then you have a Moon-bounce Helical.

There is one advantage in locating the coil in the antenna - it can be made physically much larger than when inside the tuner. Double dimensions and coil Q is also doubled. There are no screening box losses either. But this advantage is not worth the trouble when, as often the case, most loss occurs in the ground.

Reg.

How do you mean 'Doc? If he currently does not have cable service then the coax will run from his wall plate to a junction box where it will hang disconnected. It doesn't get connected until he subscribes to a cable service. The cable company then sends a tech out to physically connect the coax to the service.
Were you referring to induced signals ?
And you are right about the ownership of the cable but if it doesn't cause any interference and he never keys while the cable guy is hooking someone else up (ouch), would there really be any harm? I think that is more of a moral decision.
Just wondering...

The narrowest you could get for a TS-440 from Kenwood when it was new,
270 Hz.

When the 440 finally dies or I hit the lotto, which ever comes first, it
will get replaced with something with DSP IF and audio.

>>don't. So given a stock tranceiver and a PSK program, I can work PSK

Thought about it but I've never been a big fan of CW. Fact is, after
about four months of using PSK, I put the key and the keyer in the
closet.

>>I have no idea where the poor dynamic range comment comes from other

In general, I would agree with the sentiment, but the realities of
the steepness of filter skirts do cause AGC problems with weak signals
on all modes, especially rigs with the technology of the 440.

Current DSP rigs have vastly better specs of course, but I don't have
one yet.

> difference Jim, not 50 dB.

The problem is usually with a weak DX station and some local new to PSK
that isn't aware that a KW is overkill in that mode. I can tell they
are running 200W because I'm monitoring them in another window, WAY
outside the passband of the CW filter, and they SAY they are running
200W.

Most would consider the ability to put a whole lot of QSOs in a small
bit of sprectrum an advantage of the mode, but YMMV.

The usual problem with PSK newbies is audio overdrive trying to get
lots of unneeded watts out creating LOTS of extra sidebands.

> There is hum and noise from ground loops, harmonic distortion (that

Oh, it does show up on the display; I see a lot of it.

A coffee versus tea arguement; I can type a lot faster than I can send
CW even with a keyer. Mostly I like PSK because a lot of power is NOT
required. I live in a very populated area, and a marginal TV fringe
area to boot. If I were to put up a full sized 3 element 20M beam, I
would be hard pressed to keep it inside my property line, and no ones TV
frontend overloads from 30W.

A good DSP program for this is chromasound. You can drag and drop any filter you want. The only hang is I can't run both the DSP and a PSK program at the same time on a single sound card. I think you could do it with two sound cards, or use two computers. A chromasound working demo is on their silicon pixels website. So far, it's the best puter DSP I've seen. It does great for CW, but if you use a SSB filter with crowded band cdx expect some blowby. But it's still way better than no filter at all. I haven't done too much PSK, but have tried hamscope a bit. I had pretty good luck with it here. The copy of MFSK16 thru 80m noise was pretty impressive compared to rtty. But the signals I were copying were plainly audible. I've downloded most the other PSK programs also, but haven't tried them yet. MK

EZNEC displays the far field at infinity. Presumably the ground wave
doesn't make it to infinity.

It was a joke, Jeff. There isn't a meter, and my message wasn't a flame.
And I certainly wasn't seeking "credibility" with nonsense such as this.

As for the fake meter, it isn't an on/off meter (on for troll, off for no
troll). It is a meter that rates a troll on a scale from one to ten. Since
this troll was so obvious, it simply doesn't rate very high as a troll in my

opinion.

However, since you control your own fake meter, you're free to rate the troll how you want. And I assure you that I will not hold your troll rating against you. [insert big grin here]

But Reg, a coil in the trunk in a shielded enclosure doesn't
radiate as much as the length of the conductor. Those coils are
quite often horizontal iron-core toroids and hardly radiate at all.
The radiation from the length of an air-core vertical loading coil
is measurable even though it radiates no more than the length of the
coil.

I'm quoting from 75m mobile antenna shootout results. The antennas
with the exposed base loading coils performed better than the whips
with the auto tuners in the trunk. In particular, 57.2 dB for a
base loaded whip VS 52.2 dB for an autotuner driven whip.

4687. Re: Isloop antenna in attic - advice??

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-12 06:24:05 UTC
From: Tom Gwilym <tegwilym@wolfenet.com>
Message-ID: <bYZq6.540$ji.233388168@den-news1.rmi.net>
Source record: 168761

Well, I managed to get the antenna up in the attic last night. I found that the best place I could squeeze it in was an open place that has about 25 inches of vertical clearance. After playing around with it, I did seem to get it tuned up on 21 mhz and had a very flat SWR and 50 watts going out of it. The only problem is that I am getting some RF back in the shack and it gets into my Astron 7amp power supply which is powering the keyer. When I key down to transmit, I hear a click (in the power supply), and the keyer shuts off. I was just fooling around using AM modulation to try to tune the antenna instead.
When I was transmitting on AM, I ran out to look at my tv which was turned on, and I didn't see anything strange. I have cable, and the tv is probably about 15 feet from the antenna.
the antenna sure is twitchy to tune, but it will go flat on the meter with a little bit of fooling around. Any ideas on how to clear up the RF problem? RF chokes around the power supply cable and the cable that powers the keyer???

That would be true if you wanted to stop the ringing in less than one cycle.
Most of the time all you want to do is clamp the voltage spike.

The motor controllers I see use either regeneration, or a dump resistor, in
those cases.

> I suppose you never saw a solid carbon resistor filed to adjust it's
value,

> this was often done for meter multipliers and shunts when accurate
> caliobration was required,

Oh I have. I have even done it myself once or twice. The problem is finding somebody who still manufactures carbon composition resistors today. Just about everyone is going metal film, and or surface mount. I had an application using a 2 watt 15 ohm carbon resistor, manufactured by Allen Bradley, which quit making them. Now try to find a replacement than will not bust the bank, if you can find one. I finally switched to the metal film version.

> I take it that you have witnessed this for yourself. ;)

Yup, way back as a kid when I was playing around with electrical stuff. Learned all about inductive ring up real fast.

> Sadly not always easy to come by once you retire

I got about a dozen from Caddock as free samples. Just call, or E-mail, a vendor. Tell them you are a consultant. ;-) Many times you can get free parts as "engineering" approval samples. Or if you can't get them free you can buy them at the 1K to 10K price, and save some money.

> Is this a bifilar winding similar to the resistance element used on a Post
> Office Box?

Yes it is. But this type of design is not very good when you are working at MHz frequencies. The flat film type is much better at high frequencies. I tried using some of those in a snubber circuit, they don't work for crap at high dv/dts. If crummy resistors don't get you, then the capacitor will. Many capacitor designs look more like an inductor at high frequency.

>
> > > Presumably this is why they generate noise up into VHF/UHF

> entirely by the passive elements in the circuit.

True. The reverse recovery blip of current is a pulse source rich in harmonics. This is what provides the external tuned circuit with the energy to ring.

>
> > The results would be similar to what happens with a step recovery diode.
>
> Ah! the dreaded Hole storage effect.

Basically yes. The PN junction acts like a tiny capacitor that must be discharged before current through the PN junction stops when the current flow reverses. The capacitor is discharged through a combination of reverse

current flow, and charge carriers crossing the junction to recombine with an opposite charge carrier.

There is also an even less talked about effect, the forward diode recovery effect. The PN junction must reach a certain level of concentration of charge carries before the junction will conduct in the forward direction. Until that condition is reached the forward voltage across the diode can easily exceed the normal forward voltage drop of a PN junction. How much of a voltage rise you see depends on the diode junction size, current level, and how fast the current rise, di/dt, is through the diode.

> On Octal bases?
> Used in Railway signalling a lot?

No. These are standard machine tool control relays, manufactured by either Allen Bradley or Square D, and mount directly on a cabinet subpanel. These relays have stackable contact heads with 4 contacts each. You can stack as many as two of these on a relay coil base for a total of 8 contacts. Each contact can be set for either normally open, or normally closed, by pulling out the contact element itself, and flipping it over, then reinstalling it in the head. There are also time delay contacts too. These work by air flowing in, or out, of a tiny bellows coupled to a switch in the timer head. A screw, or thumb wheel, sets the rate of air flow, thus the time delay.

> either. Otherwise, at what elevation angle does accuracy kick in ?

That's not correct. Ground wave signals are rapidly attenuated with distance, more so as frequency increases. The ARRL Antenna Book has graphs that show this. Beyond the few miles of range where the ground wave signal has faded below the noise level, EZNEC is as accurate at any angle as any program which does include ground wave analysis. (This can be easily verified by running NEC-2 with ground wave analysis enabled, or with EZNEC pro if you have it.)

But I'm sure you know this, since I've explained it several times before on the newsgroup and it's easily verified. Don't you realize that repeating something you know to be false casts doubt on the credibility of everything else you say?

> But I don't think any severe measurement problems will occur by

>
> The radiation patterns along the ground and at very low elevation
> angles of 1/4-wave and 1/40-wave ground-mounted verticals are not
> very different from each other. But EZNEC won't show it.

You really should run these analyses with EZNEC before saying what it will or won't do. Anyone who is interested can do the following with any version of EZNEC, including the free demo version available from http://eznec.com (details will be different if you're using a DOS version):

1. Start EZNEC.
2. Open example file Vert1.
3. Click "FF Plot" to generate a 2D elevation plot.
4. In the plot window, click "Save As", give the file a name, and click "Save" in the file dialog box.
5. Open the Wires Window by clicking on the Wires line in the Control Center (main window).
6. Change the wire End 2 Z coordinate from 10.3 to 1.03 meters. This reduces its length from about 1/4 to about 1/40 wavelength.
7. Press the <Enter> key to accept the change.
8. Run "FF Plot" again.

9. In the plot window, click "Add Trace", and select or enter the name of the trace you just saved.

You'll see the patterns of two verticals of length about 1/4 and 1/40 wavelength overlaid. Judge for yourself whether the patterns are the same at low angles. (Be aware that this model doesn't include ground resistance loss, so both model antennas are 100% efficient. If you do include the ground system loss as a resistor or by using the High Accuracy ground model and radials just above the ground, you'll find that the 1/40 wavelength antenna is really a lot less efficient unless you have a very elaborate ground system.)

If you are for some reason interested in knowing the intensity of the ground wave field, use the "near field" analysis, which does include the total field. Do this for the 1/4 and 1/40 wavelength antennas if you're interested.

What's the rule of thumb for initial tuning adjustment of a roller coil L tuner into ladderline? The manual on my T tuner says to tune the roller coil for max rcvr noise, and then the two var caps. After that, put low pwr carrier in for fine tuning. Does this also apply to L tuner circuits with roller coils?

> carrier in for fine tuning. Does this also apply to L tuner circuits with
> roller coils?

About the same. Using the noise can get you pretty close as far as the coil goes. You want to use the least amount of coil to get a match. So say you peak the noise, and tweak the caps, and you have a good match. After that, I keep slowly lowering the coil turns and tweaking the caps until I can't get a decent match. Then I go back to the point of least coil and acceptable SWR. This way you are assured of being tuned at the most efficient point. Most of these tuners can do a match with 49 different settings of coil/caps. Only the setting using the least coil is fairly efficient. So there is really only one correct setting if you don't want to waste power. I did a test of the losses with different tuner settings on this MFJ-989c I have. I found if you use too much inductance, 20% loss is easy to come by. Of course, many will say you can't hear the difference, and they are probably right, but I still hate to just throw away available power. If you run an amp this 20% can build up a lot of heat. I found if you are very careful with the tuning, the loss can be almost unreadable on a normal wattmeter. MK

I don't think that they do, if you look carefully towards the end of whatI
have atempted to demonstrate mathematically you will see that I credit your
proposition with an improvement of up to 1 dB improvement in Signal to noise
Ratio, but this is at the expense of a loss of a great deal of dynamic range
of the reciever and the introduction of all sorts of internal problems down
the receiver chain not least of which is running the predetection filters at
far too high a level. If you consult the literature about high 'Q' filters
you will see that the recomendations suggest that you operate them at as low
power levels as practicable to prevent ringing etc.

I'm sorry if I miss inerpreted a request for a source of a preamplifier as a
query.
I mistakenly assumed that as you request a pre amplifier that you had not
yet undertaken any practical observations. I was trying to save you some
money. When I last looked for the commercial device offered by one of our
reputable dealers such amplifiers were going for about 250 UKP approx US$360
I decided that for a dB improvement at 160 m that was uneconomic for me.
I might conclude differently now that PSK31 has become so popular.

I can't be bothered to go back through the postings in this topic but somewhere this garden size was mentioned. This raised my interest as due to my personal circumstances I live in the centre of a town to be near to the shops and Doctors etc. My backyard is 25' x 65' approx and I am looking for an antenna that will operate satisfactorily on long wavelengths. I know that I shall have to pay a huge efficiency debt for my practical situation, but so be it, I think it prudent to know what I am walking into before I set out. I had hoped that free and frank discussion in this so convenient medium amongst fellow experimenters would not only be pleasent, but also useful to all concerned. If in my quest for vigour I have upset you by a too search approach then I appologies. Never the less the facts remain the facts.

So what is the gain of the reference AE?

> It might be as much lower as 12-20 dB (QSB, sorry), but it very
> obviously is much less than 29 dB down.

My figure of 29 dB is due to the absolute efficiency not the comparative gain compared to an uncalibrated reference.

>
> And your numbers come from what stone tablet???

OK a readily accessible reference that many Hams will have is
"RSGB RADIO COMMUNICATIONS HANDBOOK"
Fig 15.6
I chose the quitest noise temperature for 160 m as this favoured your case
the most.
In fact the sky temperature can be up to 45 dB hotter at 160 m
than the low of 9,000,000°K that I chose for my worked example.

> sources.

Just how do you launch the signal to make this measurement?
Is the calibration signal that you use a Frauenhoffer wave
or are you in the near field. Do you make your measurements with the
energising probe in different positions with respect to the Aerial under
measurement? The position of the launching probe in the near field is
critical and highly variable.

> >However the S/N ratio is still less than that at the I/P from free space
to
> >the antenna.
>
> How do you know that?

please follow the example for (Si/Ni) / (So/No)
This is all standard work and can be verified in any good standard text on
the subject of noise and receivers or transmission theory. It is used every
day by millions of competent engineers and the results always come up
trumps. They have fitted the theory for the last 70 plus years. Now I will
be the first to admit that this is not conclusive proof of the absolute
correctness of the theory, that would suggest a closed mind and an infinite
knowledge of everything past present and future, of course such a God like
quality may be confered by others, but I would still remain unconvinced in
the absoluteness of the theory.
In the mean time because it works not only for me but millions of others I
have no proven alternative to hand I will continue to use it untill
convinced that it is flawed. I would hope that I am amongst others in such
an objective approach not only to this hobby, but to life.

This is the bit that you should attempt to understand.

> >or approximate 1 dB loss of signal to noise ratio.

Her is the bit that ses that for any system the signal to noise ratio out of it is always worse than what you put into it because a perfect syatem does not exist and any practical system will always add some noise of it's own.

"Send reinforcements I'm going to advance"
I won't bother to rehearse that one as you are no doubt quite familiar with it.

> >reduced the dynamic range of the receiver by 30 dB in the example.

And her is wher I credit your contention that the amplifier gives an improvement. If you can afford the price and you think that 1 dB using SSB will give you a worthwhile advantage then please go ahead it is your money after all. At least you'll get some benefit on 28 MHz if your Rx doesn't already have a built in RF Amplifier

> You are pulling numbers from the thin air instead of staying with a
> working example. That's often a problem when people ask a simple
> question, and get an answer from a textbook.

Had you provided data I would either have accepted or disputed the data provided, had I been content with the data then I would/will rehearse the exercise using your data. In the abscence i used data which is freely available to the majorioty of Hams who can do the calculations for themselves. Ther will be readers to this excgange that are quite unfamiliar with this topic and I had hoped that by exercising it for your benefit that the dialog would be in a small measure a teaching exercise or at least a basis for considered debate. As far as I am concerned I am not out to win an

argument, merely preventing the little grey cells from becoming completely atrified in retirement. I shall go out kickiong and screaming to the last, no graceful resignation to the inevitable. I have no objective to accumulate laurels, (I have enough of those thank you), nor do I have the objective of denigrating any other living soul I am motivated to find like inquistive minds and wher possible give encouragement to those just coming through the hobby and who wish to go a little further than the requirements of the examination required for certification.
There is life after the RAE

> 1.) The FT-1000D, which has a fairly good receiver by amateur
> standards, has about 10dB S/N with a .2 uV input signal and 2.5 KHz
> selectivity.

((2 x 10^-7)^2)/50 = 8 x 10^-16 Watts
10 Log (8 x 10^-16) = -150.9 dBW

Converting to dBm as this is the usual units for receiver calculation due to the scales of the available instruments used.

= -120.9 dBm calibration signal

Now this value is producing 10 dB S/N
therefore threshold is -131 dBm

the bandwidth 2,500 Hz = 34 dB Hz

-131 = -198.6 + 34 + 10 log(T)
TdB = 33.6 dB
Tr = 2,290.9 °K

NF (in dB = 10 Log(1+ (Ts/290)
= 10 log (1 + 2,291/290)
= 10 Log(1+ 7.9)
= 9.5 dB

This is the typical noise figure for a mixer with no RF amplifier.
They are usually about 10 dB

> That's a NF of 20 dB, or a temperature of almost 29,000°K.

I think that you are a decimal point out OM
2,900°K is nearer the right figure and you will find most RX with solidstate mixers and no RF amplifier have this sort of noise figure.
A good balanced mixer with the correct Local Oscilator injection level will come up with this sort of figure fairly consistently and have an insertion loss of a couple of dB

> 2.) The sky-noise you are using is not accurate at every location,
> every season, and every time of day. It is also most likely for a
> non-directional antenna.

No indeed it is not ther is a variation of some 45 dB which is mean medicine in anybodies language. I chose the best case, the case that would favour

your contention. The hotter the sky gets the worse having an RF becomes. Try using the switch attenuator fitted to many modern RX on top band you'll need it all. On 20 m during the mid-day noise peak 10 to twenty dB is probably the setting. I would like the possibility of putting in 3, 6, 10, 20, 30, 40 dB but I have not seen such a receiver so an external switched attenuator is an advantage. You want just enough attenuation to knock the noise back without attenuating the signal to a level below the receiver noise.

> Ignoring the above is NOT a good idea, when answering a question.

I stated the parameters for my example. I'm sure that many will not be following the maths as it is without putting a load more calculations for other values, however if you are prepared to accept that I won't cheat I'll publish a small table of results of improvement of S/N and reduction of dynamic range for a variety of sky temperatures.
My aim is to assist, contrary to any differnt opinion which you may have formed. :)

> >It would help if you could provide some AGC to the preamplifier.

> No, that is NOT true at all. AGC to the preamplifier would only work
> when the desired signal was into the AGC response. As a rule, overload
> and IMD comes from signals outside the passband of the receiver.

That is precisely why you don't want excess front end gain. The IMD will only occur when adequate levels combine in a non linear device, this is withing the set despite the fact that the signals originate exernal to the set. the object of the exercise is to keep those signals out of the set. you can do this best with a pre input filter with nice steep sides and a very large rejection ratio. Using amplification only makes those signals larger and more difficult to eliminate. Leakage around and saturation of the filter etc.

> AGC would have no effect on the systems IMD performance on weak
> signals...where it is most problematic.

Here you should use a filter immediately at the aerial of at least three sections and 18 dB/Octave rejection to out of band signals.

> More important than this, you are dictating my system works
> differently than it actually does.

I think that if you look carefully that I support some of your contentions, but do not completely share your conclusions.
Take a look at my web page for my background click on the picture of me, (The good looking one), for a mini technical bio. with pictures.

www.gary.peach.dial.pipex.com

> >If you are working machine modes the fraction of a db signal to noise
will

>
> Nonsense.

This is a table of counted errors in a known passage of text 1,000
characters long. The relationship is
P[E] = 1- erf(S/N)

erf is a function that you can look up just like logs
P[E] is the statistical probability that an error will occur in a noise
environment with a signal to noise ratio S/N
This works for speechs in parliament, trying to communicate across a noisy
machine shop or in a railway station etc.
It does work well and NASA use it ALL of the time for statistical analysis
of the data from their deep space spacecraft.

| ERRORS
S/N | per 1000
0.1 dB | 147.85
0.2 dB | 138.64
0.3 dB | 129.68
0.4 dB | 120.98
0.5 dB | 112.56
0.6 dB | 104.43
0.7 dB | 96.60
0.8 dB | 89.08
0.9 dB | 81.88
1.0 dB | 75.01
1.1 dB | 68.48
1.2 dB | 62.28
1.3 dB | 56.43
1.4 dB | 50.92
1.5 dB | 45.76
1.6 dB | 40.94
1.7 dB | 36.46
1.8 dB | 32.31
1.9 dB | 28.50
2.0 dB | 25.00
2.1 dB | 21.81
2.2 dB | 18.92
2.3 dB | 16.32
2.4 dB | 13.99
2.5 dB | 11.91
2.6 dB | 10.07
2.7 dB | 8.45
2.8 dB | 7.04
2.9 dB | 5.82

3.0 dB | 4.78
3.1 dB | 3.88
3.2 dB | 3.13
3.3 dB | 2.50
3.4 dB | 1.98
3.5 dB | 1.55
3.6 dB | 1.20
3.7 dB | 0.92
3.8 dB | 0.69
3.9 dB | 0.52
4.0 dB | 0.38

> >Presumably on transmit you feed your other antenna which you say is of
> >comparable gain with 400 kW for full ERP ;)
>
> ?? Did I say that? Or did you imagine it?

Please observe the emoticon, technical discussion can be a lot easier with a
little humour. This may be an innovation for you but the old hands do it all
of the time, except for a very few old stick in the muds. Their loss. :(

> >> My FT-1000D barely makes that level with 10 dB internal S/N ratio
> >> preamp on, and that is for wider-than-SSB bandwidths! On CW, forget

I saw that somebody else had independently addrressed this point so I will
not restate the excellent advice so given.

> >Of course it sounds stone dead,
> > but the S/N ratio of any CW signals that you receive will be great.
> > Once again if you work PSK31 you will not be able to
> >hear the signals, but they are there none the less, and if you can tune
to
> >them they will decode without error. HamScope is a great application for
> >this purpose.
>
> Nonsense.

Try it and see, you'll be pleasently surprised.
Just look at the numbers of Hams coming up on PSK31.
Ask some of the truthful old CW ops that have tried PSK31.
You'll get a lot more new countries with this newly available to Hams mode
This mode was what we were using to get the images of Mars back from
Mariner IV in 1966. The system temperature was 40°K and the bit rate was 8
BPS in a 2 BLo bandwidth of 8 Hz. Lots of good fun several hours per
picture.
The round trip light time was of the order 20 Minutes. (don't mean to blind
you with science. The bit errors had to be less than one in 1,000 for the
scientific analysis team to accept the data. (That's the guys that look at
the pictures and say there are no little green men on Mars)

> PSK is not as effective as the human ear on CW (assuming you know
> morse code, and have normal CW skills) for digging signals out of the
> noise.

History will decide that debate I think.
I would love to understand this myserious facility that CW ops claim to
have.
I wouldlike to see a series of experiments done in an attempt to quantify
these claims. If they are proved significant then ther is a great deal more
to be done with machine encoding and communication in a noisy environment.

> Readability is far better on CW than on PSK, when all things (gain,
> receiver bandwidth) are equal.
>
> It's better get back to consider there things by fact, not hearsay.

I fear that this discourse has become so long that the content is now lost
and anything which I have to say further to amplify the facts for you and
those trying to follow this debate, (they probably gave up ages ago), will
have to be in a seriously edited version of this post.

I wish you luck and I am so pleased to be able to debate such technical
issues with somebodyt as equally dedicated to learning and understanding the
truth of nature.

Actually the integral of the phase shift is detected, since this builds up
over the duration of the bit time the S/N is enhanced. If the detection
process relied only upon the instantaneous phase change then I doubt the
system would work at all.
I recommend Viterbi
"Phase-Locked Loop Dynamics in the Presence of Noise by Fokker-Planck
Techniques"
Proceedings of the IEEE Vol 51, No 12 pp. 1737-1753, December 1963

to answer your deeper questions on Phase Shift Keying.

If you can lay your hands on NASA technical report No 32-819
Theory of Practical Design of Phase-Locked Receivers Vol 1
by Robert C. Tausworthe
Jet Propulsion Laboratory
California Institute of Technology
Pasadena California
February 15, 1966

The theory is set out simply and the essentials are shown in an appendix.

You'll just love the pictures :)

Other authors to look for are Jaffe & Rechtin, Davenport & Root
And if you can find a rare document by Robert C Bunce July 1963 for a full
mathematical treatment at elementary engineering level in manuscript form.

NASA Re-Order No. 63-211

It will assist you if you have a knowledge of servo techniques.

DSP filtered radios are OK if you don't stack strong signals near
them. They really need a conventional filter ahead of the DSP, like
the new Yaesu has.

>> We sure don't have an AGC problem with all modes! Virtually all other

>on all modes, especially rigs with the technology of the 440.

I'm not how the 440 behaves. There is absolutely no reason to have AGC
problems with off-frequency signals. That happens only if something
overloads ahead of the narrow filter.

I do not experience that with any of my rigs, unless there is an S
meter pinning signal.

>Current DSP rigs have vastly better specs of course, but I don't have
>one yet.

They certainly have impressive reading advertisements, but I won't be
using one anytime soon untill the close-spaced dynamic range is the
same or better as conventionally filtered rigs. I have enough problems
being bothered by clicks from close signals as it is.

>The problem is usually with a weak DX station and some local new to PSK

>200W.

Why should that bother you?

>Most would consider the ability to put a whole lot of QSOs in a small
>bit of sprectrum an advantage of the mode, but YMMV.

It would be nice if the systems had reasonable dynamic range. They
don't, because of the modulation and filtering schemes.

>The usual problem with PSK newbies is audio overdrive trying to get
>lots of unneeded watts out creating LOTS of extra sidebands.

My FT 1000D generates harmonic distortion that is only about 25 dB down no matter where the gain is set. PSK ops tend to think that minus 25 dB or more is "excellent" spectral purity. -50dB will get you lynched on CW, because people are used to having strong signals next to weak ones without QRM.

>> There is hum and noise from ground loops, harmonic distortion (that
>> does not show up on your IMD display), and even less than perfect
>> carrier and sideband suppression in a few rigs.
>
>Oh, it does show up on the display; I see a lot of it.

You can only see it if you are using a wide filter and the signal is somewhat strong. It does not show up on the "IMD" reading.

I see PSK ops with harmonic distortion all the time getting excellent signal reports. Most likely because the harmonics are outside the passband of the receiver. One cure for that is to use a high pitched tone all the time, so the SSB filter eliminates or reduces the IMD.

Many SSB transmitters are not designed to provide the low harmonic distortion required when driving the audio with a tone that is used to provide RF output. Collins tried that for generating CW in the early S line, and users constantly had complaints about spurious signals when operating CW.

99% of the whining by PSK ops about "high power" would vanish if the system had decent dynamic range. PSK ops simply don't understand the system isn't as good as they are led to believe. They think the problem is caused by an extra 10 dB of transmitter power, when the real problem is poor system dynamic range. When normal propagation variations can well over 50 dB spread in signals, it's silly to think that everyone running the same power will cure things.

If PSK was a closed loop system, things would be a lot better.

Hi Cecl,

The largest problem is stray capacitance lowers system efficiency, not
a lack of contributing radiation from the inductor.

Any shunting C at all at the base of the antenna, or in the lead from
the antenna to the loading inductor reduces system efficiency. You
always want the capacitance of the antenna to dominate the system.
That's why the inductor, even if the system is base loaded, should be
positioned so that the coil is above sheet metal. That's the reason
longer slender coils work better in many applications.

Stray capacitance is the reason everyone measures higher loss by
locating the loading away from the point above the antenna mounting.
Tuners are especially bad, becuuase they really add a lot of stray C,
lowering the Q and increasing current in the inductors.

Not so on all cable systems.. ours though we dont subscribe is connected all
the time- they sell the desrambling box upon subscription and install that..
As Doc says it's still a poor Idea.. just asking for problems. IMHO.

Mark:

I believe that he was asking about adjusting an "L-Tuner" and not the "T-Tuner" which is what you described.

Although I have never owned a "store bought" L-Tuner, I believe that the tuning procedure is much different, than for a "T-Tuner". The "T-Tuner" has three adudjustable elements, usually two capacitors and one inductor. While the "L-Tuner" has only two adjustable elements an inductor and a capacitor.

There will usually be a method for, and a tuning step, of configuring the L and C into different orientations with respect to each other in the circuit to get them into the right configuration to effect the matching, which complicates the process.

When the correct orientation of the L and C are found then there will subsequently only be a single setting of inductor and capacitor which matches a given situation of reactance cancellation and impedance transformation.

And so the tuning procedure for the "L-Tuner" is probably quite different from that of a "T-Tuner" which often has many different settings of the three components to effect an impedance transformation, and no configurations to arrange.

Yes Ed you can. There are several manufacturers of what look like center loaded antennas for UHF. They stand about 31 inches high and are listed as 5 BD gain antennas but are also spec'd at 3 dB w/o the plane. The only catch with them is that you have to look for the ones which state that they are intended for non/G.P. service. They have extra parts inside to make them tune correctly.
The same goes for half wave offerings which stand about 12" high and are spec's at 2.1 dB w/a G.P., unity gain w/o. You can see such at the Antenex.com web site.
The other option is to install a ground plane kit, which consists of some adhesive backed copper strips and a device which will connect them to the mount but you'd have to remove whatever liner is in the topper to install the kit properly.
One other thought, whichever antenna you choose, make sure that the mount is designed to work with the thickness of the surface that you're going to mount it to. The 3/4" mounts (commonly called Motorola mounts, or NMO by Larsen) are limited in the range of thicknesses they will successfully work with and are offered in several sizes.

That may be true, Tom, but consider mounting the one foot long loading coil (taking care to reduce stray capacitance) physically inside the trunk of a car with an external nine foot whip VS mounting the one foot loading coil externally on top of the trunk with a nine foot whip. That's a nine foot radiator VS a ten foot radiator. That one foot difference is measurable.

Hello all,

I wanted to make a 1:4 balun for a dipole or wire antenna, to be used
with my FT-817 (max. 5 W)

What kind of core, size and dimension do I need ?

what AL value is best to cover 3,5 to 30 MHZ ?

and how many bifillar turns do I need ?

Thanks for the help in advance
73's

You seem to be ignoring antenna impedance. The impedance of the
1/2WL dipole would be low. The impedance of the one WL or two WL
dipoles would be high. What are you using for a transmission line?

Steve- you should try complaining to the Yahoo groups people. Once-
Fracky cut me off the list when it was egroups, because of something I
said here. I asked the support people to look into it (I had had no
notice)- HIs reaction was quick and a real temper-tantrum- But- he put
me back on the list.

Apparently they told him to be good and live up to their "terms of
service". If I remember right, keeping you off the list for something
that did not happen on the list is a violation. It might be interesting
to see what their reaction is.

I have left the list, voluntarily, since then. I left because there was
nothing there. No posts were published without editing by fracky to
comply with his views.

news:3AAC6354.4EDFAB8C@IEEE.org...
> But Reg, a coil in the trunk in a shielded enclosure doesn't
> radiate as much as the length of the conductor.
============================

Of course it doesn't - it radiates nothing at all - it's shielded
!

In any case, perhaps I didn't make it clear that the length of
conductor involved with any radiation is that portion of antenna
length which is replaced by the coil when it is taken out of the
tuner box and inserted in the open air at the the base of the
antenna.

If the overall height of the antenna is unchanged by inserting a
loading coil at its base then the radiation resistance must also
remain unchanged. It follows that radiation from the coil is
exactly the same as from the straight length of antenna conductor
it has replaced.

(If otherwise, where in the ARRL bible is it shown how to calculate
the radiation resistance of a solenoid. Marconi never seemed to
latch onto the idea either.)

Neither is the current distribution along the antenna changed by
inserting a loading coil at its bottom end - so again, no change
in radiation resistance.

The length of antenna conductor the coil has replaced is the same
as the length of the coil. (It has nothing to do with the length of
wire on the coil).

Of course, if by inserting a coil the height of the antenna
increases by the length of the coil (say by a few percent) there
will be a small increase in radiation resistance and a
corresponding small increase in field strength.

If your measurements show a considerable increase in efficiency
when the coil is moved from inside the car and re-located in the
gap created by cutting 6 inches off the bottom end of the antenna,
the overall antenna height remaining unchanged, then either the
coil has a higher Q (it is bigger and has fewer turns of thicker
wire for the same inductance) and hence lower loss, or your
measurements are in error.

Compact automatic tuners have terrible Q coils (20 AWG in mine).
An increase in Q from 100 (inside tuner) to 400 (big fat base
loading coil) may improve field strength by 6 dB if ground loss is
small.

(Incidentally, if ground loss is small, there is little or nothing
to be gained by shifting the coil higher up the antenna as is often
advocated. Top-capacitance loading is much more effective and
efficient. Unfortunately it has a higher wind resistance.)

As a sanity check, use EZNEC to insert a zero-loss loading coil at
the bottom of a vertical above a perfect ground and check that
input (radiation) resistance remains unchanged. If it DOES change
then there must be something wrong with EZNEC.

You may have noticed I havn't mentioned Thevenin, Pollard, Norton,
Maxwell, non-dissipative resistance, Foster, reflection,
reciprocity, superposition, swr or even conjugate match. They are
SO confusing. ;o)

The improvement is much more than that, because the receivers sound
"dead" on the antenna when there is no amplifier. I can NOT hear any
noise from the antenna when using narrow filters, and the receiver
audio is required to be nearly full-on. Not a pleasant situation when
a S-8 signal appears.

Your "books" may disagree, but that is how it works. I suspect the
reason for the error is the "book" poredict much higher noise than
really exists at times, and people tend to ignore the directivity of
the antenna which reduces noise.

>Ratio, but this is at the expense of a loss of a great deal of dynamic range
>of the reciever and the introduction of all sorts of internal problems down
>the receiver chain not least of which is running the predetection filters at

Non-issue. I am NOT amplifying my transmitting antennas.

The strongest signals are typically only in the range of -40 dBm. My
receivers barely have problems handling my own transmit signal, which
is only +20 dBm.

>> What query? I made no query. I offered real-world data, since I have

>approach then I appologies. Never the less the facts remain the facts.

Your answer was incorrect, the fellow who lived in the UK and who
asked the questions verified he DID need an amplifier, as does
virtually EVERYONE who uses an antenna like he described.

When theory predicts the opposite of the results of dozens of people,
it's time to look for the mistake in the "theory". I suspect it is
because of ignoring some things, and being too conservative in others.

>> That array, after feedline losses are deducted, is typically slightly

Certainly it is nearly 100% efficient. Gain would generally reduce the
noise, not increase it, unless the noise was primarily coming from one
direction.

Hmm, so you are now telling me a 3/8 wl vertical over 100 3/8th wl
radials in an open pasture on farmland is less than 10% efficient?

I don't think so. I think your numbers are incorrect. You are assuming
the noise is higher than it is, and ignoring the directivity of the
receiving antenna.

>> And your numbers come from what stone tablet???
>

>your contention. The hotter the sky gets the worse having an RF becomes. Try

Your best case is clearly incorrect. Your advice to the other
gentleman was incorrect, and he knew it. He knew it because he did an
A-B test and found he needed an amplifier, just like I and many others
have found.

I suggest there are two major errors behind your mistaken advice:

1.) The noise can be and often is a lot lower than the RSGB book
indicated.

2.) You ignored directivity of the antenna.

Cecil, W6RCA wrote:
"The radiation from the length of an air-core vertical loading coil is measurable even though it radiates no more than the length of the coil."

Placement of the coil may affect radiation. Terman says: "An analysis of the sectionalized tower is given by G.H. Brown in "A Note on the Placement of the Coil in a Sectionalized Tower", "Broadcast News" no. 22, p.14, October, 1930.

I notice that Terman`s drawing of a "sectionalized tower" places the loading coil near the top. Wouldn`t that lengthen the high-current section of the shortened tower?

Best regards, Richard Harrison, KB5WZI

But Reg, if a loading coil is inserted at the base of a whip, it's obvious that the antenna length increases by the length of the coil. Nobody is going to chop off their whip just to keep the antenna length the same.

> The length of antenna conductor the coil has replaced is the same
> as the length of the coil. (It has nothing to do with the length of
> wire on the coil).

Nobody said it had anything to do with the length of the wire on the coil. The inserted coil adds linear length to the antenna for any given whip.

> Of course, if by inserting a coil the height of the antenna
> increases by the length of the coil (say by a few percent) there
> will be a small increase in radiation resistance and a
> corresponding small increase in field strength.

Yep, that's what I'm saying. We have measured that effect at the 75m mobile antenna shootouts. The difference between a 11.5' whip driven directly by an SGC-230 autotuner VS that same 11.5' whip riding atop a Texas Bugcatcher coil was 4 dB.

> If your measurements show a considerable increase in efficiency
> when the coil is moved from inside the car and re-located in the
> gap created by cutting 6 inches off the bottom end of the antenna,
> the overall antenna height remaining unchanged, ...

Reg, nobody is going to chop off their whip to maintain the same overall height. They will simply insert the coil under the existing whip.

> (Incidentally, if ground loss is small, there is little or nothing
> to be gained by shifting the coil higher up the antenna as is often
> advocated.

The inductance required to resonate the mobile antenna goes down as the coil is moved from the bottom to the middle. Less inductance means less wire in the coil and less I^2*R loss.

> As a sanity check, use EZNEC to insert a zero-loss loading coil at
> the bottom of a vertical above a perfect ground and check that

Yep.

> I plan to use some RG 58 type coax for the TL, say about 10 feet long.
> Would there be any special concerns?

If you are going to use coax, go with the 17.4" each element. You
can obtain more gain (directivity) with a 7.25' center fed dipole
but some sort of matching network is usually required. Your first
attempt with the dipole will probably not be resonant on exactly
161.45 MHz.

Cecil wrote:
"You seem to be ignoring antenna impedance."

Yes, and another problem is that current reverses direction every 1/2-wavelengh of travel in the wire. The 1/2-wave dipole is fine, and radiated broadside to the wire without extra lobes produced by interference between radiation sources of opposing phases.

Extensions to the dipole have reversed currents and so produce reversed phase radiation unless something is done to avoid it.

Colibear arrays use phase inverters at the ends of the dipole and every 1/2-wavelength thereafter, Often the phase inverter is a short-circuited 1/4-wave stub.

Best regards, Richard Harrison, KB5WZI

Peter- these comments are fine, but I would like your views on the
"differential T" tuner, like the MFJ986. This has only two controls,
and, supposedly, only one final setting for a given combo of load
characteristics and tranformation.

I don't necessarily disagree about asking for problems, just wondering where
the problem was. From my experiences, even though the cable company rents
you the box they still disconnect the cable when service is stopped to keep
you from buying a "pirate" descrambler. That is what Time Warner/ AT&T does
anyway. YMMV

Hi Fred,

If anyone has a basis for suit for defamation of character, it is that poor lawyer who made the mistake of taking on fraudtenna as a client.

However, the legal folderol aside (being meaningless in a hobby based forum) I appreciate your posted example of fractal humor.

I am glad of one variation however. I note there is no reference to "possible legal consequences." Another, is the notable lack of public correspondence from herr doktor - no doubt due to "possibly legal consequences" which could translate into conformance to a court order to cease and desist on his own part. The judge "could have" offered to ameliorate this if fraudtenna simply apologize for its slanders, and fraudtenna "could have" simply rejected that option in favor of the restraining order. - to each their poison ;->

Well, anyway Fred, I am sure you took careful stock of the situation and confirmed that your construction efforts did not abridge the pending rights of fraudtenna :-O

PUBLIC NOTICE TO FRAUDTENNA, AND ITS MINIONS

In the way of pubic notice to fraudtenna, I am thinking of a design for which I will soon submit a patent application and I hereby order you to cease all operations in this field of endeavor and to surrender all documents relating to my idea to me immediately. As my idea has coverage of a patent pending status, you are hereby ordered to cease and desist. If you fail to act in the next 3 or 4 years, I may be forced to take the first step toward a "possible legal action."

;->

Taking food out of your children's mouths? The Saddam plea....
Thankfully the reference to the flag wasn't waved again, I having
fought for it while the right winger's coddeled and bought and paid
for deferrals kids spat on me in uniform - I am glad for that at
least. It was tough enough with a non-smoking doper as president, and
now the conservatives have aced that with a non-inhaling crack smoker.
No wonder compassion is such an ephemeral and ambiguous thing. :-)

I have moved quite often in my life, at the beck and call of the US Military for 26 years. It was the military that put me here in harms way so that I could preserve you and your children's freedom. Let me count the ways, California three times (twice in earthquake prone territory), Japan (earthquakes every day so it seemed), and here in the great northwest (when it was commonly supposed there was no earthquake problem). And if I suffered any from these assignments its my own damn fault (consistent with the attitudes of those coddled children at least - fruit not falling far from the tree and all).

There's choices for you. And still no kiss ;->

I think we've proven at the 75m shootouts that the longer the bottom
section is before encountering the coil, the stronger is the signal
(for antennas without top hats).

You are absolutely wrong Reg.

You have neglected capacitance from the base of the antenna to the
vehicle, and of the inductor and the lead to the base of the antenna
mount.

That capacitance can not be ignored, because it increases current
dramatically in the coil and contributes nothing to radiation.

The added length would NEVER account for the large FS change you see.

That FS change is caused by the current in the inductor being reduced
when the area beyond the inductor does not have shunt capacitance
directly to ground.

Even the smallest amount or parallel capacitance hurts efficiency a
noticable amount.

>Yep, that's what I'm saying. We have measured that effect at the

No doubt. Think of the reduction in shunting capacitance after the
inductor.

You have that backwards Cecil. The inductance required increases as
the coil is moved up in the antenna. The radiation resistance of the
antenna also increases.

Reg is correct, if most losses are concentrated in the coil rather
than the ground, base loading is every bit as as good (or can even be
better) than top or mid-loading.

In the real world, that often is not the case. Espoecially if you use
the poor ground systems Reg often advocates using. In that case,
moving the inductor higher increases efficiency because radiation
resistance increases faster than inductor ESR.

>> As a sanity check, use EZNEC to insert a zero-loss loading coil at

>Where can I get one of them thar zero-loss loading coils?

Download "solenoid" and you will come close. You can design inductors
with Q's in the thousands in a virtual inductor.

Just don't try to build one.

Yep, my autopilot suffered a massive brain fart. I was picturing
current decreasing so I^2 decreases, inductance increasing as the
square of the turns, while resistance increases only as the turns.

What exactly has sounding dead to do with signal to noise ratio, perhaps you
should advance the AF gain a little if you like to hear the noise,
personally I find it tiring and back it off until it is barely audible.

> I can NOT hear any noise from the antenna when using narrow filters,

It is also possible to build your own amplifiers in the UK,
though sourcing the components can be a bind at times.

Wow! even our US$36,000,000 paraboloid could only make about 60%

> Gain would generally reduce the noise, not increase it,

How can you make such a statement.
If I have a quantity ofnoise power Pn and I put it through an amplifier the
out of the amplifier I get G Pn.

100 mW of noise into an amplifier with a gain of 10 will give me a watt of
noise out.
Additionally the amplifier will not be perfect so it will add some noise of

its own in fact if I measure carefully I'll have a little more than a Watt
of noise out.

> unless the noise was primarily coming from one direction.

The amplifier does not care from whence the noise comes.
>

Why should it be more efficient?

> I don't think so. I think your numbers are incorrect. You are assuming

If the receiveing antenna is a 3/8 vertical then it will have no
directivity.

I could quote people like Hogg and Mumford (Bell Labs), but just how many
hams would have them on their book shelves?
I chose a reference that many people in this hobby might have.
Had the ARRL Handbook actually had anything on Sky Noise then I would also
have refered to it.

> >Just how do you launch the signal to make this measurement?
>
> I don't "launch" noise, I receive it and measure the level. It is
> launched by storms and other distant noise sources.

Your snipped example outlined a calibration process using a coherent signal,
in order for that signal to enter the Antenna it would need to be launched

into free space.

> >measurement? The position of the launching probe in the near field is

For future reference you might like to use the chart in the ARRL Handbook
12.2 Fig 1 "Relationship between noise figure and noise temperature"

> >> 2.) The sky-noise you are using is not accurate at every location,
> >> every season, and every time of day. It is also most likely for a
> >> non-directional antenna.

The figure that I use is that published in the literature, as the discussion
is of a general nature then one can only use that which is generally
accepted to be the case. The original work that was done in order to publish
these figure would not be bassed upon a single observation but a controlled
and verified experiment.

> >No indeed it is not, there is a variation of some 45 dB which is mean
medicine

>
> Your best case is clearly incorrect. Your advice to the other
> gentleman was incorrect, and he knew it. He knew it because he did an
> A-B test and found he needed an amplifier, just like I and many others
> have found.

I suspect that your observations show what might be expected when the
receiver input is terminated in what is little better than a leaky resistive
load. An amplifier will produce produce an increase in the hissing sound,

but it will not show any appreciable improvement in Signal to Noise ratio.

> I suggest there are two major errors behind your mistaken advice:

Perhaps others would like to comment in order to break the dead lock.

> 1.) The noise can be and often is a lot lower than the RSGB book
> indicated.

I chose the lowest figure of actual sky noise.
If you see lest than this amount out of your attena then it is lost due to the inefficiency of the Antenna. In fact this method if the sky noise is known at the time of measurement is a good way to calibrate the efficiency of an Antenna.

> 2.) You ignored directivity of the antenna.

Directivity will assist where noise is man made.
Such man made noise is over and above the natural sky noise which is uniformly distributed at the low level which I chose for the calculations in my example. If additional noise at these frequencies was from a thunder storm thenm directivity would change things, however the noise from lightening is over and above the base noise used in the examples.

I would like to direct your attention to
Page 12.3 of the 1987 ARRL Handbook
middle column, last paragraph before the sub heading 'Selectivity'.

"Typical noise figure for a good receiver operating
below 30 MHz runs about 5 to 10 dB,
Lower noise figures can be obtained,
but they are of no real value because of
the external noise arriving from the antenna."

"It is important to remember also that optimum noise figure in an RF amplifier does not always coincide with maximum stage gain ...

>Reg.

You've often said you don't know what a troll is. That, Reg, was a troll. You know that (as Cecil once again pointed out) that EZNEC doesn't display ground wave signals as part of its far field results. And you know why, since I've explained it many times on this newsgroup. The troll is getting a little stale, though. You're a clever person, so surely you can come up with another one?

4737. The Best Wire Ant. in the Business

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-12 20:15:42 UTC
From: "radiosigs@mindspring.com" <radiosigs@mindspring.com>
Message-ID: <98jea6$o08$1@slb7.atl.mindspring.net>
Source record: 168716

A 20 METER "CLOUDWARMER"
I thank you for showing an interest in my antenna which was voted theA number one wire antenna is North America by an independent research organization: AF2Y Enterprises! I did NOT invent it; the idea was given to me by WB2OTK in South Carolina. He didn't invent it either. Who then did? I don't know; I don't care; all I know is that it works like a BOMB! Furthermore the U.S. military is using it under the name N.V.I.S.(Near Vertical Incidence Skywave). In 30 years on the air, it is the best wire antenna I've ever used and can easily challege commercial beams for effectiveness.

A few basic concepts to begin with. A "Cloudwarmer" is a MONOBAND 2 element wire beam. I stress MONOBAND and it can be erected for ANY BAND. Secondly it is based entirely on mathematics and is uncomplicated. Thirdly, all that's required is standard wire, 52 ohm coax of any length and five insulators. Also I do not recommend using a tuner because if the construction is correct and adjustments,if necessary are made, a tuner will be unnecessary and furthermore it may mess up the mathematical relationships which govern this antenna. Lastly, any ham who can set up a standard dipole can EASILY construct a Cloudwarmer. And if any ham cannot construct a standard dipole, then he or she has no business being on the air therefore delete this information and take up basket weaving!

Keep this in mind because it applies to any Cloudwarmer for any band. The "Warmer" consists of a driven element called a dipole with a parasitic called a reflector the latter of which is 6% longer and placed between .15 and .2 wavelengths below and parallel to the driven element or as NEARLY parallel as possible. THAT'S IT. It is also known as a "SCATTERBEAM" because the RF hits the ionosphere at high angles and then scatters all over the world. It is a COMPLETELY NON-DIRECTIONAL ANTENNA on the order of a vertical but better than one for INTENSIFIED OMNIDIRECTIVITY.

Now for the mathematics. Let's talk about the numerical figures regarding wavelengths. Let's say a 20 meter HALF WAVE dipole is to be constructed to resonate with a very low SWR at 14.300. Using the formula 468/frequency , we see that such a dipole must be 32.7 feet which equates to 32'8". Let's now convert that to inches. 32' x 12 =384 inches +8=392 inches. That's a HALF WAVE. Double it and we get 784 inches therefore we now know there are 784 inches in a FULL WAVE dipole FOR 14.300. The reflector we discussed which ALWAYS GOES BENEATH the dipole i.e. driven element can be between .15 to .2 wavelengths in distance. What then has to be the length it we place it, for example .15 wavelengths below? Simply multiply 784 x .15 and we come out with 117.6 inches and divide by twelve to convert to feet and we get 9.8 which is 9 feet,10 inches. That is the minimum distance the reflector must be placed underneath the dipole. The maximum is .2

wavelengths and to change that to feet multiply 784 x .2=156.8 inches, divide by 12 and we come up with 13 feet. We now know that the reflector can be placed from 9 feet, 10 inches to 13 feet below. MIne is at 10 feet; supposedly increasing the distance will give more gain but I do just fine right where it is.

The reflector must be 6% LONGER than the dipole. We already know the length of that dipole for 14.300 is 392 inches. Multiply by .06 and we get 23.5 inches which is 23'6" and that's the length of my reflector.

So now with the math done, we proceed to erect that Cloudwarmer. Put up a dipole 16'4" from either side of the center insulator and feed it with any length of, for example, RG8U. Take an SWR reading and WRITE IT DOWN..it's VERY IMPORTANT.
Next, string out a relector wire about 10 feet below and about 2 feet LONGER as parallel as possible. Each end should terminate in insulators. There is NO ELECTRICAL CONNECTION between it and the driven element dipole nor is there any electrical connection between it and the coax feed. It just hangs there minding its own business but is nevertheless the secret to success!

Now take an SWR reading with everything in place. If you see ANY change whatsoever, good or bad, LEAVE THE INSTALLATION ALONE! It's working! If there's no change then either LOWER the reflector 6" at a time or LENGTHEN it by a few inches. What we MUST see is a change in that SWR. Once it happens, go work the world and YOU WILL.

We know that a dipole less than a full wavelength high has a multilobular pattern with appreciable ground loss. Now when we use a vertical at ground level, we must add radials. Why? Because we must minimize ground loss. The radials are RF collectors meaning that the emitted RF instantaneously is picked up by them and RETURNED to the base of the vertical to be RERADIATED at about 15 degrees to the horizon. That reflector acts just about the same way. It MINIMIZES ground losses by reradiating the RF into the "clouds" at much higher intensity than will a standard dipole and your signal will be heard in places you never knew existed. The Cloudwarmer has APPRECIABLE gain on receive versus a standard dipole and vertical-REMARKABLE GAIN. And on transmit, try switching back and forth between it and another antenna and see what happens. The person on the other end will be STUNNED!

4738. Re: G5RV Dipole -- Works?

4739. Re: 160m preamp for RX antenna ??

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-12 20:46:42 UTC
From: Mike Tatum <miket@cybatek.fsnet.co.uk>
Message-ID: <3AAD35B1.41CD3640@cybatek.fsnet.co.uk>
Source record: 168711

Woa there !
I think you've got your knickers in a bit of a twist Gary!
(And I mean it in the best possible way!)

Firstly, I'm Mike Tatum, I posted the original article.
I live in the UK.
I have a garden that is 40ft x 40ft.
I have a small receving antenna for 160m that requires a preamp.

Let me explain how I came to this conclusion without using any numbers at all :

I use a homebrew vertical antenna for transmitting on 160m.
It's great, it's small in comparison to a wave length, but it works and I've
made contacts across
the atlantic using it, and I'm very happy with it!

I decided to look into ways of improving my _receiving_ capability on 160m, as
this is as important
if not more important than getting a big signal out.
(I learnt this very quickly!)

So, having a small garden, yes just 40ft x 40ft, I had to think small!
A rather neat antenna for receiving became available to me and I bought it,
paid real cash for it too!

Having made it resonant on 160m I attached it to a small lightweight rotator
and put it in the garden.
The first thing I noticed was the _HUGE_ nulls off of each end, using my
FT1000MP receiver I have measured
the null to be around 60db.
(No maths please!!)

So, I started to listen around 160m one evening, I often struggle with QRN on
the vertical,
switching to the receive antenna I note a distinct drop in S reading but an
even further drop in noise,
such that I can hear stations that aren't detectable on the vertical.

Swinging the RX antenna around I am able to null out the source of the noise
making the
stations fully readable, but without any S reading at all.

Next I borrowed a 25db gain preamp from a good friend, Bob (G4VGO), he's not
into maths either, but he knows his stuff!
(And my girlfriend thinks he looks like father christmas, but that's another
story :))

Anyways, I connected the preamp up and did some more tests.
Listening to a station in the Azore Islands I tuned the best I could using the vertical antenna, the guy ended up being
about a 3/9 with +10db of QRN.

Next I switched over to the RX antenna, swung it round so that the noise source was in one of the deep
nulls off the end of the antenna, immediately I noticed that I could hear the Azore Islands station perfectly, no S reading
but _perfectly_ Q5 ... I took a deep breath and switched on the preamp, WOW!
(Still no maths !)

The noise level came up to around an S1 but the chap in the Azore Islands was now 5/7-8 with me !
PERFECT!
At this point I pinched myself a few times to make sure I wasn't dreaming!

Just to prove it I switched back to the vertical, +10db of QRN and just about able to hear the chap, switched back to
the rx antenna perfect 5/7-8 fully readable and indeed a pleasure to listen to, switched back to the vertical +10db of noise,
back to the RX antenna 5/7-8 perfectly readable ... etc etc etc ...

Now, I'm a relatively simple chap when it comes to numbers, I work with computers all day so I let them worry about the numbers,
but one thing I know for sure is "I need a 26db preamp" it works, it does what I want in my 40ft x 40ft garden in little ole England!

So chaps, I really appreciate all the help and good intentions, honestly I do!
... but please, lets not start a nuclear war over this,
after all I only wanted to know where I could buy a 26db gain preamp from !

Thanks and I hope this was a fun read!

Mike Tatum.
(A small radio ham in a small garden in a small country with an even smaller receiving antenna!)

: Well US patent law is changing so that all patent applications will be
: published, I think, 12 months after the initial application date. This
: will then by like EU patent applications.

I was recently told that it was going to be 18 months. I would
hope that this would give USPTO an incentive to speed up the process. I
have two that were filed over a year and a half ago that I have yet to
hear about. Just had another one allowed, and it will have taken almost
two years from filing to issuance.

>
> Bill-W4BSG
[snip]

I believe that antenna tuner setting are a really a simple concept explainable by elementary theory of simultaneous equations. Consider...

A ham radio antenna tuner has to accomplish only two things.

One: Cancel an arbitrary constant reactance, call it "X".

Two: Perform an arbitrary constant impedance [actually resistance] transformation ratio, call it "r".

Mathematically speaking you have just two constants, X and r and some relationships to set up with unknown adjustable element values. And when you adjust the tuner for a reflection coefficient null, [reflection coefficient null is VSWR = 1:1] you are really just manually computing the solutions to a set of two simultaneous equations. The antenna tuner and ham handed combination is really an analog computer solving two simultaneous equations so to speak...

Now if you have an adustable network with N adjustable but previously unknown element values within it, that is indeed capable of cancelling an arbitray constant reactance X and setting up an arbitray constant impedance transformation ratio r, then mathematically to find the settings for those N unknown element values in terms of the two known constants X and r, you have to set up and solve 2 equations for N unknowns.

Such a system of 2 equations in N unknowns is what mathematicians term an overdetermined system.

With exactly two equations and two unknowns the solution can be and usually is unique. This is the situation for the "L-Tuner". Nice neat uniqe answer with a setting that achieves perfectly zero reflection coefficient [VSWR is 1:1 exactly] but the inductance value you end up with may not be as low as the corresponding inductance value for a "T-Tuner". Then again it could be lower... caveat emptor.

[The one situation where two equations in two unknowns may not have a unique solution is that when the "determinant" of the equations equals zero, in that case all solutions are possible I guess. But this is a highly unusual circumstance.]

On the other hand, when there are just two equations and N elements to be set, depending upon the nature of the equations, there may be many solutions. This is what makes "T-Tuners" such fun!

In the theory of simultaneous equations, if you have 3 independently adjustable elements to set up two constant relationships represented by an arbitrary X and an arbitrary r, then there can be multiple solutions for the 3 unknown element values to satisfy the two equations to do that. This is the situation for the "T-Tuner". Generally several settings will work, and hams strive to use the one with the smallest inductance value, to reduce losses. Since inductors are lossy compared to capacitors.

Now with the "Differential T-Tuner" like the MFJ unit to which you refer, you do have three adjustable elements. However the two capacitors are ganged together on one "adjustment" knob and so can't really be set inedpendently. This represents a set of two equations with three unknowns but with a "forced" constraint or relationship between two of the unknowns.

In this situation, you might just "luck out" and hit one of the several solutions right on the nose, but the probablities of that happening are slim and none.

On the other hand you will likely only find one setting of those two knobs which "minimizez" the reflection coefficient. And in all probablility you will not be able to satisfy the two equations exactly, just approximately. And so... what happens is that often with the "Differential T-Tuner" you will not find a "perfect" zero of the reflection coefficient, i.e. you get a single "dip" in reflected voltage but it does not dip to zero. In VSWR terms you can't always reach VSWR = 1:1 with a differential T-Tuner. But they are easier to adjust when you can find a dip. There may indeed be situations when you can't even find a good enough dip to satisfy your transmitter. Even then there is not guarantee that the inductance setting is low loss either. It trades off convenience in adjustment for a lower range of adjustment and potential situations that can't be tuned which could be tuned by a T-Tuner with relative ease. And so... I personally would stay away from the differential T-Tuner. Sorry MFJ.

All that being said, if you use circuit theory techniques to set up these two equations equaling X and r for the various antenna tuner configurations, you will find that they are not "linear" equations, rather they are "multi-linear" equations and so... you will find them a little harder to solve than the ones you dealt with in high school algebra classes.

Best,

-Peter K1PO

4745. Connector probs and IC-706MKIIG vs FT-100D

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-12 22:56:42 UTC
From: storkus@packard-hell.storkus.com
Message-ID: <98jk79$1c8$1@nnrp.atgi.net>
Source record: 168621
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,alt.ham-radio.vhf-uhf

Ok, the connector question first since it's the most important: I have the new IC-T81A quad-band HT from Icom. Unfortunately, they chose to stick an SMA connector on the radio instead of, say, a TNC (which is what I would have chosen, but YMMV). I've found a couple of sources so far for SMA males (including the very expensive, but also very helpful Pasternack Enterprises), but I'm having some mechanical problems. A local radio shop here has some SMAs for RG-58-style cable that they were using for a local cab company that had a computer system that could receive GPS. These connectors are crimp-style. Unfortunately--despite the fact that they swear up and down that they're using the right size for the ferrule--the connector wobbles inside the ferrule and cable, eventually losing contact (i.e., becomes intermittent) on the shield as it flexes.
Now the tech at Pasternack said to me today when I called that the connector should be rock-hard when crimped properly--no wobbling of the ferrule and cable whatsoever! And everyone's told me that clamps will break clean off when flexed repeatedly. And while the Pasternack guy had no real opinion of the solder-type connectors (looking at them, though, I'm not sure how much of a difference the solder would make mechanically, anyway), the local radio shop says that they had poor results with them.
My original idea was to use an SMA to TNC or N adapter and then put the latter connector on the cables--this becomes more important when a base setup is used, where I intend to use LMR-400 (RG-8 size and performs a LOT better than 9913 both mechanically and electrically for only a fraction more) or LMR-600 (even bigger and lower loss) and SMAs are no longer possible.
So I'm sure, in these 3 groups, there has to be a few microwave people reading or maybe some guys who work in a commercial radio shop and need to do GPS or 800 MHz land-mobile or maybe even cellular (including 1800 or 1900 MHz PCS). Remember, this needs to work at 23cm (1300 MHz) reliably!

The second question is one that seems to pop up more and more, but the answers keep changing, so I'll ask again: I'm thinking, sometime in the future (maybe this summer) of getting an HF rig. An all-mode that works up to 70 cm would be real nice: that brings in the IC-706MKIIG and the FT-100D (and maybe the 847?). Reading around, this is what I've found:

Icom IC-706 MKIIG

Advantages: microphone and headphone jacks on the faceplate
mechanically built well
electrically built well as far as the basics go
the plethora of mods
computer-controllable

Disadvantages: lack of filters
DSP sucks (better in the G model?)
poor performance with strong signals (poor IMD rejection)

Yaesu FT-100D

Advantages: Filters rock!
DSP rocks too!
Easier to use (?)

Disadvantages: sucks mechanically (knobs fall off and feel "mushy", pigtails for leads)
Loud fans that STILL don't seem to do the job!
Lots of stories out there of blown finals and drifting osc's.
Yaesu customer (dis)service

This last part in particular worries me. I've bought quite a bit of Icom stuff (in fact, I may have to send in the quad-bander for a little battery pack problem) before, and I've NEVER had a problem with their customer service regarding parts or returns. The stories I've seen floating around about people sending in FT-100's THAT ARE STILL UNDER WARRANTY and having to pay or otherwise getting lots of static really worry me, especially considering how I hear a LOT about the radio falling apart (sometimes literally!). It doesn't do any good to have "the better radio" when it doesn't work! Despite all the faults in Icom's radio design (something I've noticed on my T81A as well, piss-poor AM rejection being up near the top) at least they work, and work reliably.
Now maybe these problems have been fixed with the new "D" version. But what about Yaesu's customer service if I need to send it in for some reason anyway?
And finally, Kenwood's new TS-2k has just come out, and has a $600 module to add 23cm capability to boot--the first to do so! (Well, since Icom discontinued their IC-900 line, anyway...) Any comments on that radio? It's pricey ($3k including the 23 cm module), and I've been hearing for quite a while now (outside the 'net!) about Kenwood's growing un-reliability, but I'm curious to find out what you all think.

Thanks for any and all info, and you can e-mail me direct at storkus@storkus.com. Thanks!

Mike

4746. Mounting DK3 Screwdriver antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-12 23:21:27 UTC
From: <>
Message-ID: <XRcr6.9052$R_6.904483@newsread2.prod.itd.earthlink.net>
Source record: 168622

Any suggestions on how to mount the W6AAQ DK3 Screwdriver antenna for an apartment installation? Before you suggest mounting the antenna on the car and running coax to my apartment, I should let you know that this is not a viable solution.

Don Johnson (who makes and sells this antenna) suggested a brake drum. Unfortunately, I'm having difficulty finding a repair shop that has old brake drums.

Any other suggestions?

4747. Capacitance hat supports

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-12 23:51:20 UTC
From: <>
Message-ID: <Yhdr6.5300$6p5.485447@newsread1.prod.itd.earthlink.net>
Source record: 168623

I recently purchased the W6AAQ DK3 Screwdriver antenna.

I know that any sheet of metal can function as a capacitance hat. The capacitance hat must be at the top of the whip in order to be most effective. But how can I support the capacitance hat? Is there something I can clamp to the top whip to support the hat?

(No, I'm not operating mobile. Thus, aerodynamics are not an issue. Also, please don't suggest mounting the antenna on the car and running the coax to my apartment.)

4748. Z-match for DK3 Screwdriver antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-12 23:52:40 UTC
From: <>
Message-ID: <cjdr6.9144$R_6.911729@newsread2.prod.itd.earthlink.net>
Source record: 168624

Is anyone here familiar with Z-matches? The DK3
Screwdriver uses one. The Z-match is supposed to be able
to tune the Screwdriver antenna for any frequency from 10m
to 80m WITHOUT turning any knobs.

I'm curious:
1. How can the Z-match tune an antenna WITHOUT requiring
lots of knob twisting?
2. Why doesn't everyone use a Z-match and thus avoid the
need to keep tuning around to get the SWR under 2?

That sounds odd. Get out to a country garage.
There will be a pile of them out back.
I just had my oil changed Saturday.
There must have been 20 discs and drums heaped up by the turning machine.

Or find any junked car or truck with a wheel still on it and pull it off.

4750. Re: L tuner adjustments

Newsgroup: rec.radio.amateur.antenna

Peter- THanks for the lesson on math that may or may not apply here. THe factors you expounded on may help in understanding some aspects of tuners, but are rarely delved into when the time comes to match the system. I really wanted your opinion on a different type of tuner that was not the "L" or the common "T"
One answer is clear- you did not catch the phrase "Differential-T" that I used. In the case of this type, there are three elements, but two are NOT mutually independent. THe two capacitors are linked, in series, between the source and the load, with the inductor (variable) forming the vertical leg of the "T". THe link is such that , as one cap is increased, the other decreases.

With the two caps having a mutually dependent relationship, there are still two variables and two unknowns, not three variables. THe effective capacity as well as the distribution are really one control, not two.

(BTW, you were about eight when I had my first class in differentials; the simultaneous situation came earlier, but I don't remember just when) :-)>>> (note the long, gray beard)

Cushcraft has a few dual band Yagis that are not that bad to carry around on
a fox hunt. You can attach the antenna to a broom handle for stabilizing.
Type Cushcraft in the search screen. Of course other antenna manufactures
make similar products or you can role your own. 73 W9FPJ

Hello. I have two of the HF5V Butternut V-A's. They work gang busters for me. I use one for camping and the other one sits on a six foot mast on the roof top attached to the chimney. I would put up a 100' tower but no space in my yard for it. My property sits in a hole in my town. I am at 800' above sea level. the house is about 25' and the tip of the butternut stretches to about 35' above the roof. So the whole outfit is 860' ASL. Lots of radials, ten of them spread out like a spider web. During one contest 15 meters opened up before I went to church. I got 21 contacts in 10 minutes SSB from Northern Europe, Central Europe, France, Spain, Ireland, North Africa and South Africa. By the way I live in Kokomo, Indiana, 50 miles North of Indianapolis. I also have a wire up in a flat V configuration. Each leg is 35' long from the chimney to the back edges of the yard to a MFJ-949D tuner and a Alinco DX70. I am very pleased with the performance of my rig and the HF5V on SSB and CW. 73 W9FPJ

Hi Mark,

I don't know why everyone goes through such worries regarding tuning a tuner.. For years (read over 45) I have used a relative field strength meter and just tuned for maximum smoke.

Why everyone wants to tune an antenna tuner by measuring conditions on the transmission line is a puzzle. SWR has never shown how an antenna is performing - just if the transmission line likes it or not.

No doubt about it. I carry extra solid masts just for this purpose. But of course, the results may be skewed a bit due to the extra length of the antenna. But on average on 75m, I'd guess I gain 2 s units to the others I talk to if I add a 3 ft mast to my almost 9 ft normal antenna. You see the difference just in the receiver before you even transmit. But I don't think moving the coil too near the top is good either. I think 50 to 75% a good range. Over about 75% up the antenna, and the coil losses start to outweigh the advantage in current distribution. My present 80m antenna in basic form has the coil at a fairly low 3 ft from the base. So it's only about 1/3 the way up. Thats one reason why I want to make a new one. It will be taller and the coil a good bit higher. But still probably not over 50-60% up. This antenna semms to work better on 75m on my car than my truck I think. I'm think I'm having a bit of the problem Tom refers to with the coil too near the body. I had thought being my coil still is a little over my cab that it wouldn't be too much a problem, but I'm not seeming to be doing quite as well as the same antenna used on my car trunk. The car roof is lower and more sloped forward. I have the antenna about 1 ft or so behind the back window on the front of the bed, and I think the coil is too close to the horizontal roof section right below it. I should have known better than to try it that close, but being alot is window I thought maybe I would get lucky. I think I'm going to move it back a bit. I've got it mounted on a piece of angle iron that goes across the bed. I can move it back fairly easy. I do have extra ground strapping from the antenna to the truck. So not totally relying on the angle iron for a ground connection.

Still pretty risky. Most of the cable installers just cut the connection
with a pair of dykes and leave it dangling next to the distribution box.
if you use that wire as an antenna, you could likely cause TVI problems
just from the close proximity to the box with the strong rf field. Most
of the other coaxes to other houses are still going to be bunched
together very close to your line. MK

Richard Clark wrote:
"I have moved quite often in my life, at the beck and call of the U.S. Military for 26 years."

Yes, but we know it was the navy. Richard Clark told us about the tower kit stowed in a canvas bag the size and color of his seabag.

From my hitch in the navy, moving isn`t all that bad. After all, everything you have has to fit more or les into that seabag. I beat the system a little with a super-sized seabag, the kind with a detachable lid, but it did take a strong back. It was of course not government issue.

When you are at sea, you move a lot but your gear stays in your locker. That`s not tough either. It`s the other hazards that might get you.

Our radio operators rotated through a watch schedule, 24-7, while we were at sea. In port, a group of ships could usually rotate the watch and a single ship could take calls for any ship in the group, and "pass the word". It was mostly monitoring because it was wartime and radio silence was the norm. My part of the navy thought VHF was line-of-sight, so if the look-outs didn`t spot any ships outside our convoy or smoke on the horizon, chatter often ensued at VHF.

The radio operator`s job was Boring. He just sat there in front of the radio with the cans on his head copying the almost incessant BUSHIPS traffic for four solid hours while writing "no sigs" again and again in the radio log. With so many ships there is seldom any traffic for any particular ship. Thankfully, I wasn`t an operator.

Since this is an antenna group, we don`t need to swap sea stories such as "the monkey in the chain locker" or the "old salt who can`t sleep ashore unless someone is splashing the side of the house with a garden hose".

Best regards, Richard Harrison, KB5WZI

Peter- Sorry I did not read far enough the first time- you DID cover the differential T. However, there is still an area of puzzlement- I just got this gadjet and have been playing with it with an MFJ 259B analyzer. I have been able to tune two different dipole antennas over thew full range from their resonance to 30mHz. Both antennas used ladder line, and the tuners internal balun. 1:1, I think)
In fact, I tuned the 255 ft dipole at every 0.5 mHz point from 1.8 to 11, and every 1.0 from there to 30. in every case I made it to an SWR of 1.0. The inductance values tend to be at the low end of the range.
With the 135 ft dipole, I went from 3.5 to 9.0 by 0.5, and to 12 by 1.0 increments. At that point I stopped, because I found a problem with the tensioner on the inductor "wiper", and let myself be diverted to mechanical repair. (The unit was a used one.)
After this short set of tests, I am pretty well sold that it is a good unit. However- I am reminded that most of the tuners on the market are NOT this type- there may be a reason that I dont see.

I'll let you know.

Danny:

Hey, up until a few years ago, I always did that as well, I didn't even use a field strength meter, I just tuned for maximum brilliance of my # 47 pilot bulbs bridged across a short section of feeder, and it worked wonderfully with those older vacuum tube PA rigs. Hey I even used a 100 watt light bulb as a dummy load.

Now with my modern solid state rigs with VSWR foldback protection circuitry, etc... it's not as easy to tune for maximum brilliance. You will often get a lot of "false" things going on with those indications as the impedance presented to the PA varies and the amp folds in and out while tuning. Running at lower power would work except there's not enough output to actuate the simple field strength meter or indicator bulbs, and so... I end up using a VSWR meter, a.k.a. reflected voltmeter and tune for a 1:1 VSWR.

I've even been reduced to using a "real" 50 Ohm dummy load rather than the old light bulb.

there is a shortened version of the G5RV that works 10-40 meters.

It is a 51 ft flat top fed with 450 ohm ladder line (Antennas West, Utah)

Also check Spi-ro Mfg for an all bander shortie.

I use the 105 ft version fed with 32 ft ladder line and have good luck with
it. It suffers
on the 10 meter band, I get some rf in the shack on that band. I found it to
be quieter
on rx than a full 80m dipole by 10 db. I have alot of noise in town.

Good luck

Rosco

Most interesting, Tom. It confirms my personal observations while
operating the mode for a few months early after it arrived.
One very quiet morning on 20 meters I happened upon several European
PSK31 stations, all very weak but barely audible on an otherwise dead
band. I tried for most of an hour to tune in one of them, and get it to
lock and print, without success. But- I was able to clearly copy the CW
ID of each and every one of them. When I reported this one RRAP it
drew the predictable response, ie of course there was something wrong
with my setup, probable polar phase shift, etc, yada yada. *Everyone*
knows that you can print PSK31 you can't hear.
Cecil insisted that "the playing field was not level". Yeah. That's it.

Here is a site with alot of 6m info.
http://www.uksmg.org/index.html

468 / freq(mhz) = length of 1/2 wave dipole.
spacing between elements of beams are usually .2 wavelengths (average)
reflector is 105% length of dipole.
director is 95% length of dipole

Quad antennas work well also, easier to build when using wire. Regular
plumbing pvc pipe can
be used to hold wire to shape. Driven element is 1 wavelength, reflector 5%
larger, director 5%
shorter, spaced 20% of wavelength. Length of driven element can be changed
to get perfect swr.
feed point can be fed direct with coax like a dipole.

you don't have to make folded driven element on yagi, you can use gamma
match or t match(hairpin).

Good Luck

The question I have is, exactly what are you measuring? Is the RF
you are measuring going to end up at a decent take off angle in
the far field or end up warming the ground?

You could put a noise filter on the power line to the radio as well. That might eliminate the problem. I have seen some vehicles that have lots of alternator noise right off the show room floor. I have seen when others never have it or it shows up a year or so later.

Maybe that meter is still pegged from a previous use.

I use an Alinco EDX-2 autotuner with my 24 ft motorhome and load a 60
ft wire that I stretch out from the top rail on the MH roof (insulated
from it) to whatever I can find to lash a collapsable 10 ft tent pole to
for the other end. I usually set the tuner unit under the MH and run the
antenna wire around the (fiberglass) outside wall to the roofline rack,
then out.
For a counterpoise I tried a 40 ft piece of 22 guage magnet wire lying
on the ground under the motor home, arranged so that it all is under the
rig. It worked so well I kept it, and the system does just fine, altho
I'm sure more efficient arrangments are possible at greater expense of
effort and detailed onsite tinkering.

Yes the cable system usually disconnects the connection in theory. But after 20 years in the cable biz I know there are many lazy employees who prefer to do the disconnects on paper rather than climbing the pole or putting up the ladder. Then there are the employees who do put up the ladder but disconnect in error the neighbors house. Most of the time the loose end is screwed into special terminator that locks the port on the subscriber tap to prevent theft of service. All in all this is a terrible idea and should not be attempted. What is to say one day you are transmitting away unaware that a employee is climbing that pole to connect someones service other than yours and he grabs the end of your unauthorized connection while transmitting 100 watts and he is thrown off the pole with a nasty RF burn. If he lives through the fall. I would come up to your apartment with my climbing gear on and climb up and down your back. I have been a ham for 30 years and in the cable biz for 20....Do not attempt that foolish maneuver... IMHO....K7FU

4780. Dipole for a 161 MHz ?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-13 05:57:34 UTC
From: audiofan@hotmail.com
Message-ID: <3aadb6b5.1758979@news.pacific.net.sg>
Source record: 168680

Hi, and a question from a newbie.
I want to build a very simple dipole for my 161.45 MHz transceiver.
According to the 234/Mhz formula, each element of the dipole would be
17.4 inches, right?
I also understand that if I extend this length at odd multiples, I
could make each element 34.8 or even 69.6 inches, right?
Would these extended lenght dipoles improve range of transmission,
other things being equal?
Am I missing anything?

Thanks
Adrian

Perhaps, but only because it was posted to nine newsgroups.

If I ran a solid copper wire up the side of my house parallel to the drop feed from the electric company (I own the feed wire, the meter box, and the house), and I connect the wire to a rectifier bridge, and LED, and a capacitor placed over my toilet (which I also own, in case you are wondering) to illuminate it at night, morally speaking, am I stealing or just picking up free energy?

(Btw, the set up cost about $8 which could buy enough electricity to run the LED for say, 100 years.)

True, but if all you have is the built in SWR meter, it's nice to know if you tune using the least inductance, you will usually be tuned with about the same settings. I don't even have a FS meter anymore. I loaned my last one out, and it's still missing in action. I need to get another one. They come in handy. I built one a couple of years ago, but it's not as sensitive as my other one I had. Actually, I hardly ever use my tuner except for experimenting with ladder line fed antennas. All my everyday antennas are coax fed. MK

Source record: 168658

Of course, a field strength meter at the ground won't tell you how much signal you're radiating at higher angles.

But if you don't make any change to your antenna, the field strength meter will tell you how much you're changing the signals at all angles when you adjust your tuner. That is, when you adjust your tuner, transmitter, or anything except the physical antenna itself, the fields in all directions -- at the horizon, along the ground, ground wave, sky wave, near and far fields -- all change in proportion. So if you adjust your tuner for maximum indication on the FS meter, you're also adjusting it for maximum sky wave signal at whatever angle you're interested in.

If you can't hear em you can't worke em. Good stuff.
a simple vertical is prone to more noise and QRM so I can symathise with
your situation.

> So, having a small garden, yes just 40ft x 40ft, I had to think small!

For many years I have listened to signals well under S1, but with excellent
S/N ratios. So I am quite familiar with this phenomenon

> Swinging the RX antenna around I am able to null out the source of the

> The noise level came up to around an S1 but the chap in the Azore Islands
was
> now 5/7-8 with me !
> PERFECT!

> At this point I pinched myself a few times to make sure I wasn't dreaming!

That all sounds good stuff, will it work on 136 kHz I ask myself? a resonant AE on that band using PSK31 or even PSK8 would permit a lot of stations, the main thing holding it up is a good AE.
However none of this negates my calculations, which are general case illustrative examples. You have here a special case. the signal to noise ratio will never the less still be about a dB worse than possible, so there is still some work to do.
Obviously the big advantage that you are using is the directional nature of the RX AE against a vertical which is notoriously noisey especially from QRM as well as the larger gathereing volume for QRN.
If you operate a beam from the UK into VK then you get a reasonable S/N however if you are at the other end the area that your beam is looking at is filled with all of the European QRM so S/N is badly degraded. Many VK ops don't bother to operate at week ends because of this problem. This is quite a different phnomonon than the one about which I started to post. If the onle inhabitants of the world were the transmitter and the AE considered such that all electrical apperatus was switched off then my example would still be valid.

> Just to prove it I switched back to the vertical, +10db of QRN and just about
> able to hear the chap, switched back to
> the rx antenna perfect 5/7-8 fully readable and indeed a pleasure to listen to,
> switched back to the vertical +10db of noise,
> back to the RX antenna 5/7-8 perfectly readable ... etc etc etc ...

Yes indeed yopu have verified just how noisy verticals are, you will never get a better S/N than that which exists in the air just around youir AE what ever it is. just how well you will be able to monitor that will depend upon the efficiency of your AE. The figures that I have produced are the target values for which you should be aiming, when you reach them ther will be no more work to do. When experimenting it is a handy idea to know wher exactly you are hoping to get and then you can take better aim for it. May you have many happy hours with your experiments.

> Now, I'm a relatively simple chap when it comes to numbers,

well I ain't no pure mathematician, much as I'd like to be.

> I work with computers all day so I let them worry about the numbers,
> but one thing I know for sure is "I need a 26db preamp" it works, it does what
> I want in my 40ft x 40ft garden in little ole England!

For a moment let us consider what the ideal would be supposing for a moment that it was possible. The real solution to your problem would be a highly directional antenna with no additional amplification because the AE would have a good efficiency and the signal would not be attenuated.
Try this for me. Insert an attenuator in the RX feed from your vertical and

tell me if you get any better S/N. a thing that I try on 20 m some times when the band appears to be absolutely flat is to put 10 or 20 dB of attenuation into the Ae line and hey presto signals, not as many as usual but signals wher previously ther were none. The ideal solution for me would be a three section tunable filter directly in the AE line instead of an attenuator. So far I do not have the components to construct such a preselector. This filter is merely the one which the manufactures of teh Receiver should have built into the box, but didn't they fitted a step attenuator as a cheap cop out (I'm running Kenwood R-5000, and R-1000 on HF) I need some top class variable caps of about 500 pF and some coils that can have the inductances switched so that the filter can be made to operate on all bands by tuning individually. three sections will give me a roll off of 18 dB/octave and should be sufficient to give me most of the noise improvement without loosing the very weak DX signals due to attenuation below the RX threshold.

> So chaps, I really appreciate all the help and good intentions, honestly I do!
> ... but please, lets not start a nuclear war over this,

I can't speak for anyone elese, but I was enjoying the discussion, that's ahy I contribute to this news group, all I need is people that can and will engage in dialogue without rancour. I have nothing to prove and even if I had I would get no pleasure from doing so.

> after all I only wanted to know where I could buy a 26db gain preamp from !

Initially I was:
a) selfishly hoping that the discussion might throw up some techniques that I could apply to 136 kHz AEs
b) I hoped to save you from unneccassary expense.

Somewhere along the way I attributed one of your remarks from poor memory to Tom.
For this I appologies profoundly.

> Thanks and I hope this was a fun read!

Yes certainly is and most instructive, thank you.

> Mike Tatum.

Would that 1/2WL dipole be the 17.4 inches (each element) one?
I plan to use some RG 58 type coax for the TL, say about 10 feet long.
Would there be any special concerns?

Thanks for the advice.

I was thinking of the case wher relays or other inductive devices are being
operated near sensitive receiving equipment such as the Ham shack where the
eleimination of any potentila source of RFI is a welcome step. I always feel
that it is better to design in noise suppression than try to fix it later
on.

Yes, there are many solutions to the problem I was rather proud of one original circuit that I developed after blowing up a lot of control transistors one many different machines. My boss thought that I'd been dragging my feet on the problem and didn't know what to do so he put somebody else onto the job that thought a simple diode would do the job net result evcen more transistors were blown. I hadn't given up on the problem in the mean time and eventually It dawned upon me what the source of the real problem was, from that point providing a solution was fairly straight forward. that's all so long ago now that it has become part of standard practice.

That regretabbly is so true, Time to go around the junk sales and flea markets and gather up a collection, some might be OK, the majority of the old ones the wires have broken away. I think that with a bit of more modern technology a better method for attaching the lead ins could be found. For some RF work they are almost mandatory.

I am, at least I'm still on the books of at least one company (CalComp) as a consultant. I have all the cards and headed note paper already printed but it still doesn't help as much as I'd hoped here in the UK :(

> Many times you can get free parts as "engineering" approval samples.

Yes that's how I came by the metrosils. Amazing how being in a big company brings forth all sorts of information and bits that otherwise seems not to exist. I can remeber wanting a special Op amp for an intigrator. I rang around everywher trying to get samples and data. and a bulk price. Then I dropped a hint that ther would be at least 16 channels with at least two per channel and the sales engineers were cueing at my office door willing to laser trim them to my specs and offering prices that would blow you out of the water. The main reason is that they have to set up a production line to produce the stuff, ther is a nreak even quantity below whicvh it is a waste of time manufaturing. swinging all of the machine into action for something that they don't really want as an order cos it'd send them broke is quite understandable.

>Or if you can't get them free you
> can buy them at the 1K to 10K price, and save some money.

I'm highly unlikely to actually require anythingin those sorts of quantities. It would be nice if Hams got together to form a buying in service so that rare components for experiments could become available to the fraternity. just how it would work I'm not sure, no doubt there are Hams with the training and skills in such an area.

at
> MHz frequencies.

It might be with a bit oif careful engineering.
I know that this is a difficult area, one job that I was asked to do was to make a safety fuse. Rocket have to have a component to light the blue touch paper. one of the problems that they were having at the time was that when the high power RADR point at the Rocket on the p[ad it would suddenly take off all on its own. The fuse was a little copper tube with some explosive in nthe tip of it and a filament to ignite it and a couple of tinned copper wires coming out of the tube through a filling of Marco Resin. This is a resin loaded with feromagnetic and resistive materials and is often used to cast precision Waveguide loads. The fues was about half inch long and about quarter inch diameter. I tried all sorts of things but I just could not get to grips with the problem or what geometry I must use to make the fuses

intisically safe from this type of RF ignition. No doubt somebody that
followed me did solve the problem. I left for Australia at about that time
to the better weather and a little adventure.

> The flat film type is much better at high frequencies. I

Yes, I wonder what would be involved in making your own compound resistors
for special RF applications, are there any chemists in the group?

> Many capacitor designs look more like an inductor at high frequency.

Sadly I have also found that to be true.

>
> No. These are standard machine tool control relays, manufactured by either
> Allen Bradley or Square D, and mount directly on a cabinet subpanel.

Ah! I was thinking of a cabinet eight feet tall standard 19" panel size
absolutely full of realays I think tey were Potter and Brumfield to control
the big S Band Wave guide switches that changed the configurations of our

wavguide runs to produce RCP or LCP to switch the various transmitters and recevers to the various ports of the AE feed horn. These wave guide switches have a lot of stored energy when they switch. I think the person that designed the controll system had a Railway background and the entire thing was all relay logic , I can't remeber in eight years ever needing to change a relay or a switch becaise it had failed. That system really impressed me for its reliabilty. Another old reliable syatem that we had was the engineering orderwire system for engineering and ops to communicate. this was a complet telephone exchange circa 1910, the wires into the frame which was of steel Un beam construction about 25 feet long and the normal 6 foot high racks all bolted together. It was shipp from the small American town where it had operated without failure since its installation in 1910 untill it was taken out of service for us in 1966. The reliabilty had been so high that it was ideal for Apollo. Certainly a testimonial to those early telegraph engineers. It installed without trouble and I can't remember at any time that it wnet down. One of my most amusing memories of that engineering link was when an Apollo took off from the Moon's surface, one of the Astronauts had snmuggled aboard a tape of the Air Force March and as they were taking off he had played it. The ops controllers went spare ther were security people running all over the place to find the sabateurs. Of course ther was never any attempt by the Russians to sabotage use quite the contrary they were always willing to assist. I'm afraid that Astronaut got a rocket. (pun intended). Play music and golf on the Moon were frowned upon by TPTB as unneccassary trivia. Frankly my personal view is that these men showd extrodinary courage and such antics did more for PR than all of the proaganda prepared at great length by the official political machine.

Recently my fuel gauge on the car has been sticking.
I think that there is some moisture in the pivot or spring that is freezing
and producing this effect.
Do you know of a way of freeing it without removing the dashboard?

The theory is sound and has been done for a long, LONG time. People do this (without the ferrite) on 160 meters (and sometimes 80 meters) all the time!
This is how it works: you take your short loop antenna (short = far less than a wavelength, definitely less than 1/10th) and shield it on all sides except one. The gap is needed because if you closed it then the magnetic field would be locked out as well by forming a complete faraday cage. But by leaving a small part open, you keep the E field out but let the H field in. In the case of regular loops like you'd see on 160 meters and long wave work (see http://www.lwca.org), the shielding does double duty to electrically balance the loop for better performance (kinda like coax). In the case of a ferrite loopstick, you stick the loop in a "can" with one end open. Coincidentally, this also makes the loopstick unidirectional.
Note that this won't get rid of ALL noise, but since the E field is much stronger typically than the H field (unless you're using a loop to transmit with, of course), a sometimes dramatic noise reduction can usually be seen, especially if you can use the loop's directional capabilities to the advantage (peaking your signal and nulling the noise source--and loops have real SHARP nulls when properly balanced and shielded!).
Hope this helps!

Mike

4794. R5 Dimensions

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-13 10:14:36 UTC
From: "James A. Sullivan" <sja6@uswest.net>
Message-ID: <3AADF30C.9385557E@uswest.net>
Source record: 168666

I just purchased an R5 and thoughtlessly disassembled it, down to the last clamp and screw. Now it is clean and reassembled, but only working on 10 and 12 meters.

I have a copy of the instructions, but the capacitor assembly is not very detailed. I put the caps back together based on the drawings and have tried adjusting the lengths as the instructions state. SWR for 15, 17 and 20 meters is very high, with little improvement after changing length.

This is the older R5, c.1989 with a hairpin cap on the 15/17m trap.

What should I try to get this working?

Jim Sullivan N7TCF

Chuckle

All you have to do to eliminate the response to electrostatic fields is AC couple the antenna, or make it a short circuit at DC.

They might have meant the (time-varying) electric field (or they might not), but it's not possible to have one field in isolation from the other. You can have a static magnetic field by itself or a static electric field by itself, but whenever you create a time-varying field, you get both magnetic and electric.

Some antennas are more sensitive to one or the other when you're very close to the antenna (considerably closer than a wavelength). But the relative responses of all antennas to E vs H fields are essentially the same if the signal is coming from a wavelength or more away. (Exception: If the antenna aperture is several wavelengths, you have to get several wavelengths away before the E/H response is the same as for other antennas.)

What you have here is a phenomenon that seems to work really well in marketing departments, but not anywhere else.

Roy Lewallen, W7EL

Source record: 168668

Any noise reduction you see is due to the directionality of the loop, not its rejection of electric fields. It'll only be less sensitive to an electric field if the field originates closer than about 1/10 wavelength to the loop, and that's because of its shape (a small loop) rather than any "shielding". The "shield" has to have a gap, which simply routes the current from the inside to the outside, so the net effect is the same as if the shield wasn't there.

Roy Lewallen, W7EL

4798. Re: 160m preamp for RX antenna ??

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-13 11:49:40 UTC
From: "David J. Windisch" <davidw@copper.net>
Message-ID: <nPnr6.86$Zj5.90@newsfeed.slurp.net>
Source record: 168569

Hi, all concerned:

This discussion of preamps reminds me that after the last time I advertised them and thought they were gone, I found another 20-odd units in a mis-labeled box ..

I have a few surplus predriver #1 boards, C 3988W, from the Drake TR7, which have 50-ohms in/out (solder posts), 20+ dB of stable adjustable gain from 100 KHz to above 50 MHz, and take 12V power. In the TR7, they were adjusted to amplify a 0.4Vpp signal to 3Vpp.

I have used several on my small loops as low-noise preamps on 160-10M. They worked fine on a very short-lived (one evening) quickie Beverage, as well.

In short, they make good small gain-blocks in places where needed.

My main rig has a 100W PA module which is driven with about 1 or 2 mW. One could use this preamp in place of the PA for QRP work.

They have gain-adjust pots in the second of 3 stages:
2N3563-SRF2281-SRF2281. Copy of schematic included.

Board is 2-3/4 X 3-3/4 in.G10, and less than 3/4-in. 'thick'. You supply 12V power, enclosure, and 2 clip-on heat sinks for the '2281s.

Any one interested at $17 ppd?

> particularly if you have been warned.

Consider the patent application process. A person applies for a patent. The application contains a handful of claims which describe precisely what combination the patent is to cover. The patent examiner throws out a bunch of the claims, says others are too broad, and sends it back. The applicant re-writes the patent to try to satisfy the examiner, and so forth. This can go on for literally years. The result is frequently a patent that hardly resembles the original, and often no patent at all. Take for example Fractenna's most recent patent "Fractal antenna ground counterpoise, ground planes, and loading elements" (6,140,975). The "Patent Case Text" shows:

"This is a continuation of application Ser. No. 08/649,825 filed May 17, 1996 is now abandoned.

This application is a continuing application from applicant's pending patent application Ser. No. 08,609,514 entitled TUNING FRACTAL ANTENNAS AND FRACTAL RESONATORS, filed on Mar. 1, 1996, abandoned, which itself is a continuation-in-part of applicant's pending patent application Ser. No. 08/512,954 entitled FRACTAL ANTENNAS AND FRACTAL RESONATORS, filed on Aug. 9, 1995, now abandoned."

The "Fractal Antennas and Fractal Resonators" (6,104,349) shows the following history:

"This is a continuation, of application Ser. No. 08/609,514 filed Mar. 1, 1996 now abandoned, which is a continuation-in-part application of applicant's patent application Ser. No. 08/512,954 entitled FRACTAL ANTENNAS AND FRACTAL RESONATORS, filed on Aug. 9, 1995, abandoned."

So you see, there's a trail of abandoned patents leading to each of these. At one time, applications 08/649,825, 08/609,514, and 08/512,954 were "pending patents", and now they're souvenirs. Should everyone have stopped making whatever was in these applications until they were "abandoned"? There's no way of telling what was in these abandoned applications, or how much modification was done to the application from the time it was submitted until the patent was issued -- in the U.S.,

patent applications aren't public. For all we know, the original patent application was for all antennas with fractal elements, but ended up being for a much more restrictive class of antennas -- or even just a test procedure. All we know until the patent actually issues is that someone applied for a patent for something. (And for that we only have the applicant's word to take for it, but there are penalties for falsely claiming that an application has been made.)

So what should we be warned about? The content of the original application? Suppose I apply for a patent to cover all antennas. Sure, it'll be thrown out (or, more nicely put, "abandoned"), but until it is, I have a "pending patent". Should you be forbidden to make, use, or sell all antennas until it is? Ok, so I apply for a patent for a broad range of fractal antennas. By the time the patent gets through the system, I end up with a patent for a way to measure antennas having at least 8 fractal elements arranged in a star-like structure made from superconducting material and driven simultaneously with 24 sources having a precise current ratio. When I apply for the patent, I warn you that a patent for a broad range of fractal antennas is "pending". What force of law do you think that should carry?

You don't need the rectifier the LED will take AC OK all you need is a current limiting resistor or adjust the transformer coupling until the lamp lights properly.
If the drop feed is a pair or coaxial, then I doubt you will couple much energy out of it
Stick a clip on torroid such as is used with a current meter. Now let's assume that the LED takes 20 mA of current at a couple of volts and the current limiting resistor drops say 10 Volts.
The power used will be 12V * 0.02A = 0.24 Watts.
In 25 years you will have stolen 52.57 kW hours of electricity.

I don't know how much you pay for your electricity,
we pay UKP0.06 /kWH approximately
so that would be UKP3.15 in 25 years.
or about US$4.57

It takes 25 years for the company to catch you
and they demand 5% interest for late payment.

0.24 Watt = 20 mA 12 V
0.476 Yr or 173.583 or Day 4,166.667 or Hr 250,000 Min
time for 1kWH = 173 Day 14 Hr 40 Min

25 Years UKP3.15 = US$4.57 @$1.45 to the pound
52.568 kWH
annual cost US$0.18
years before getting caught, interest 5.00%
1 Yr $0.19
2 Yr $0.39
3 Yr $0.61
4 Yr $0.83
5 Yr $1.06
6 Yr $1.31
7 Yr $1.56

8 Yr $1.83
9 Yr $2.12
10 Yr $2.42
11 Yr $2.73
12 Yr $3.06
13 Yr $3.40
14 Yr $3.76
15 Yr $4.14
16 Yr $4.54
17 Yr $4.96
18 Yr $5.40
19 Yr $5.87
20 Yr $6.35
21 Yr $6.86
22 Yr $7.40
23 Yr $7.96
24 Yr $8.55
25 Yr $9.17

It is quite obvious that 5% interest rips you off far more than the
electricity that you steal.
In the UK the lecrickity companies run a scheme where you pay up front;
so that it amounts to you giving them an interest free lone for a year.
Whose the bigger crook?

The fault is great in man or woman
Who steals a goose from off the common;
But what can plead that man's excuse
Who steal a common from a goose?
The Tickler Magazine 1 Feb 1821

I heard a case of a man that had a green house very close to one of the
large broadcast transmitters. He wound a loop around the roof of the
greenhouse and from the current so derived from the transmitter he was able
to heat the green house, old flourescent tubes provided light at night.
I can't remember if he was prosecuted.
The question is, had a prosecution against him been successful would that be
precedent for him to charge rental for the passage of the waves across his
property?

> (Btw, the set up cost about $8 which could buy enough electricity to run
the LED for say, 100 years.)

Please see my table above, by the time that interest or inflation is taken
into account $8 would only buy you 23 years worth.

>Dick W0EX

There is always a little overzealousness when a new mode comes along.

I've tried a few software packages, and get the same results. I can copy signals on CW I can't print on PSK. Many others report the same thing Dick, although it is not well received by PSK fans. Digipan seems to work as well as anything else, so that's what I mainly use.

The main argument to the contrary seems to come from people who can't work CW very well.

I especially chuckle at complaints about strong signals wiping out copy on adjacent channels. There is a misplaced notion all problems would disappear if everyone runs 30 watts, instead of nasty things like 200 watts.

This reminds me of a fellow many years ago who bought a brand new FT-101. He demanded everyone else quit running "high power" because his receiver would get totally wiped out. I remember him raising hell with a fellow who was running less than 100 watts, accusing him of having a couple kilowatts. I still picture that guy at a Hamfest, face all red and veins popping out, yelling at a guy (who actually ran 100 watts) and accusing him of running kilowatts. Of course the real problem was in his brand new FT101 had very poor dynamic range.

New things are always oversold.

Anyone who remotely understands skywave circuits would know the power stuff is a bunch of horse feathers. If the system had acceptable dynamic range, it wouldn't be bothered by 80 dB or more of signal level difference.

And you are right, factually you can not print signals that would be Q5 on CW...unless you have wooden ears.

Peter wrote:
"And would 34.8 inch per element be a full WL, and 69.6 inch be 2WL?"

Let`s see. The formula I remember is V=FxLambda, so Lambda = V/F

V= The velocity of the radio wave
V= 300,000 km/sec = 300,000,000 m/sec
F= the frequency in Hz
Lambda= Wavelength in meters per second

So, Lambda = V/F = 300/161.5
(million/million=1)
Lambda = 1.858 mtr = 1.858x3.28ft. = 6.1 ft.
Lambda = 6.1x12inch = 73.1 inches

Lambda/2 = 1/2-wavelength = 36.56 inches

Reduce antenna length by 5% for "end effect"
0.95x36.56 = 34.7 inches. = dipole length
Each side = 17.36 inches

Best regards, Richard Harrison, KB5WZI

Mike,

Probably the easiest route to take on your connection problem, would be to pick up a SMA male to BNC female adaptor and put it on the rig. Use a BNC patch cable from there to the main antenna coax, long enough to avoid strain on the rig connection when the rig is moved - maybe 2". BNCs work fine at 1296 and are more available. I'd stay away from TNCs. They are hard to come by, are generally more expensive and quality is highly variable. Large coax (RG8, etc.) directly connected to the HT is NOT a good idea! Too much strain would be introduced to the rig's SMA and it could break. The patch cable would allow you to change antennas easily, too. It's unlikely that one antenna is going to cover the four bands, anyway.

On HF rigs: I have an early "706" which works well but it's not great on the receiver end. It's handy for mobiling, though. I also have a FT 847 which I recommend highly for both base and mobile use. Three local hams have the FT 100. Two of the rigs have been great, the other has been back twice. You pays your money and takes your choice!

An active antenna can be Faraday shielded to eliminate capacitive (electrostatic) coupling between the active part of the antenna (the ferrite rod) and external nearby sources of noise.

The Faraday shield is, by definition, not short-circuited. If it is, it then becomes a short circuit for the desired electromagnetic signal. A length of coax braid that is open-circuited (grounded at one end only), is an excellent Faraday shield, which means that the desired electromagnetic wave can proceed unattenuated through the shield.

The incoming electromagnetic wave is "re-created" beyond the inner surface of the shield.

Direction finding loops have used this idea for at least 70 years.

The gap is needed because if you closed it then the magnetic >field would be locked out as well by forming a complete faraday cage. But >by leaving a small part open, you keep the E field out but let the H field >in.

While that idea is popular, it isn't correct. The shield does not act like a shield at all, because it has a strategically placed gap. The gap allows the actions of the signals on the "shield", to spill over and drive the conductor inside the loop.

The "shield" becomes the antenna, and it responds to both electric and magnetic fields. You can not have an antenna that radiates or receives that does not respond to "both fields". They are inseparable when time-varying. If they are not time-varyng...your receiver will not hear them.

>In the case of regular loops like you'd see on 160 meters and long wave >work (see http://www.lwca.org), the shielding does double duty to >electrically balance the loop for better performance (kinda like coax).

This ONLY happens if you properly ground the "shield", so the "shield" is balanced. It also makes no difference ove the same antenna without a "shield", if the antenna is properly balanced. Unless something in the system is poorly designed, the shield does nothing at all.

If (as is often done) the gap is placed at the feedpoint, and the shield grounded at one side of the gap, you create a severe balance problem. The antenna would be better off without the "shield".

>In
>the case of a ferrite loopstick, you stick the loop in a "can" with one end >open.

The can will act like a shorted turn and kill the sensitivity of the loopstick. With a loopstick, the gap MUST run parallel with the rod the entire length of the rod and both ends must be open. You can have no "short" across the gap.

>Coincidentally, this also makes the loopstick unidirectional.

Even if in a can with one open end, the loop will not be unidirectional. It will be dead in all directions. Forcing a unidirectional pattern from the "reflection" of a can, if that was possible, would kill sensitivity of the antenna.

> Note that this won't get rid of ALL noise, but since the E field is much >stronger typically than the H field (unless you're using a loop to transmit >with, of course), a sometimes dramatic noise reduction can usually be seen,

The claim noise is an E field is a myth.

Noise is NOT predominately any field "gender". It is just like any other signal in the world. If you are close to the source, there can be a dominance of one field or the other...but either field can be dominant. As a matter of fact, it is most likely that most man-made noise sources are magnetically dominant or somehat neutral in the induction field area because most are radiated by relatively low impedance wiring, like long power lines.

As Roy Lewallen points out, move a fraction of a wavelength and the field impedance changes.

>especially if you can use the loop's directional capabilities to the >advantage (peaking your signal and nulling the noise source--and loops have >real SHARP nulls when properly balanced and shielded!).

While the peak is poorly defined, the null is very useful for nulling local noise sources. If you have local noise sources, a loop can definately help by nulling them out. If you have sky-wave noise, a loop is pretty much a waste of time.

There are a lot of myths about loops, mostly because we assume noise is somehow magically different than a desired signal in the way it radiates or propagates. Unfortunately articles, web pages and amateur publications do little to correct these myths, and are often respoonsible for keeping them alive.

Small loops can help if noise comes from one fixed direction, and nulls can be placed to attenuate noise. They also might allow you to move the antenna physically away from the noise source. Otherwise, they pretty much do nothing.

Ramsey electronics is selling a "Signal Magnet Noise Reduction Antenna." They claim that "This antenna responds only to the magnetic field of the desired signal and ignores the electrostatic field..." Ramsey says it is a ferrite rod, varactor tuned, active antenna that's Faraday shielded "so it responds only to the magnetic field"

What do you guys think of the theory behind Ramsey's antenna? Is it possible to use shielding to prevent the E component of the EM wave from reaching the antenna (while letting the M component through)? Sounds kind of weird to me.

Bill, CU2JL/N2CQR wrote:
"Ramsey Electronics is selling a "Signal Magnet Noise Reduction Antenna". They claim that "This antenna responds only to the magnetic field of the desired signal and ignores the electrostatic field."

Like most advertising, the case may be overstated but contains a grain of truth.

Directional loops are impaired by unbalanced capacitive coupling to their coils. That is why direction-finding loops have Faraday shields.

Terman says:
"Such a shield insures that all parts of the loop will always have the same capacity to ground irrespective of the loop orientation or of neighboring objects."

If all parts of the loop have the same capacitance to ground, they are also balanced at their null position to the traveling wave`s electric field and don`t respond. That null may be directed toward an interfering signal or noise. So, the shield can improve the signal to noise ratio.

Dr. Cohen is the father of fractal element antenna technology and what a
wonderful and useful field that is:-)

We heard this type of Lewallen nonsense when the first patent came out.

Then the second patent came out.

(surprise!)

Then the third patent came out.

(surprise!)

3 issued patents so far.
Many,many patents pending.

I geuss you can go to a patent attorney and say golly! Cohen missed something!
Let's apply for a patent on it! It's not in this patent's claims! Sure! You can
waste your money any ol' way you want:-)

Surprise!

Smile:-)

Can't fight with success:-) But you can sure try to mislead others and even
infringe on their IP like Roy Lewallen .

Surprise!

As I said, much is happening 'offline'.

That's not the point. The point is getting the power to the antenna in
the first place. What the antenna does with it is another matter. A
tuner isn't going to change the takeoff angle.

4813. balun vs swr

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-13 15:27:00 UTC
From: ON4CLN <on4cln@qsl.net>
Message-ID: <8%qr6.12631$ou.855565@afrodite.telenet-ops.be>
Source record: 168587

Question:
Suppose I make a balun "by the book" like described in numerous ARRL publications.
Suppose I wanted to measure the SWR from 80m to 10m.

Can I just connect a 50ohm dummy between the 2 balanced terminals, or is this not the right way to go? And if not; how can I correctly measure SWR?

Waiting for help...

Peter wrote:
"Since I don`t own an SWR meter, is it possible to tune the tx (it`s actually a 12-V set) and triming the antenna for peaking of the 12V current?"

If you cut the antenna as calculated, you won`t need to trim it to resonance if it is placed up and in the clear.

In tuning for max using d-c current into the radio as an indicator, the first problem is insensitivity of your indication. The second is that you may be tuning for reduced efficiency instead of increased power output.

A 1N34 or similar diode in series with a microammeter works for me as a satisfactory rf indicator. Just connect one end of the diode to the correct meter terminal and its other end to a 17-inch (more or less) piece of wire. Connect the other meter terminal to another 17-inch piece of wire. You now have a field strength indicator. Tune for maximum.

Another respondent declares the E-field much stronger than the H-field. Actually both fields contain the same energy as they beget each other in space.

Best regards, Richard Harrison, KB5WZI

My question was a little more subtle than that. At the 75m mobile
antenna shootouts, we don't measure the near field. So why is a
far field strength measurement superior to a near field strength
measurement?

Cecil,

I don't know what you are smoking but I feel you are off the subject..
The subject is as I understand it is on tuning ANTENNA TUNERS and a FS
meter works very good for that purpose. Far field, near field or
inbetween field makes no difference...

Hi Cecil,

If I remember correctly, you guys were typically within 10 wavelengths
or less and could have been measuring the more complex near fields
whose geometry is notably different from the typical vertically
polarized signal - as launched.

However, I also think you were far enough such that this consideration
didn't really amount to much (expect to explain some curious readings
perhaps).

All right i can use the news server again :-)

I have to design an antenna that has to be integrated in the future
cellular phones, for receiving also the digital television. I suppose
that the phone will have a second antenna for the >1 GHz band, or the
same antenna will be switched in some way to work in another (higher)
band. It does exist a model by samsung, SCH-M220 , a cell that can can
also be used to watch tv, but it incorporate a wire telescopic
antenna. It's not an original idea.
I was thinking of some new idea, like fractal, spiral patch
antennas,because they are broadband and compact.
Do you know some ideas, studies?

Thanks in advance,

Tiziano

More likely it's the "sending unit" located in the tank.
Overfilling-"topping off"- the tank excessively can cause this.
Sometimes it has to be replaced to correct the problem.

>ratio will never the less still be about a dB worse than possible, so there
>is still some work to do.

The calculations were negated before they were made, because they were based on incorrect data. They also ignored noise reduction by directivity, and considered the receiver much more sensitive than most are.

>Obviously the big advantage that you are using is the directional nature of
>the RX AE against a vertical which is notoriously noisey especially from QRM
>as well as the larger gathereing volume for QRN.

"Gathering volume", whatever that may be, has nothing to do with ultimate S/N on low frequencies like 160 meters.

The directivity of a small loop is such that it is mainly vertically polarized, so polarization is also not an issue. The small loop does not have significantly more directivity that the vertical, but it will allow us to null noise from a single direction (or two if you are very lucky and they are about 180 degrees apart).

The only reason a small antenna is better is because it can be moved away from a very local noise source, and can be used to null a local noise source.

>If you operate a beam from the UK into VK then you get a reasonable S/N
>however if you are at the other end the area that your beam is looking at is
>filled with all of the European QRM so S/N is badly degraded. Many VK ops

It is generally quieter looking into the UK from a distance than from the UK across a tropical region, as long as the path does not cross tropical regions.

QRM is normally not defined as "noise". Noise is normally considered to be random broadband interference. What we hear on 160 meters is a collection of many noise sources, most of which are arcs and sparks either in nature of man-made devices.

There is a several dB noise increase when I focus my arrays on the towns of Barnesville and Forsyth, both several miles away. At night time noise level increases ten or more dB, even without storms in North America. The directions with propagtion have much more noise

than others, and that noise is strongest looking into tropical zones
all other things equal.

>don't bother to operate at week ends because of this problem. This is quite
>a different phnomonon than the one about which I started to post. If the
>onle inhabitants of the world were the transmitter and the AE considered
>such that all electrical apperatus was switched off then my example would
>still be valid.

The example is not valid because the data used greatly overestimates
background noise, or you misread or misapplied the numbers.

>Yes indeed yopu have verified just how noisy verticals are, you will never
>get a better S/N than that which exists in the air just around youir AE what
>ever it is.

That simply is not true. My most effective receiving antennas are
verticals, as a matter of fact I do not have a single horizontally
polarized receiving array. My high dipole, 300 feet off the ground, is
quieter during the daytime than my transmitting vertical but it is
less effective because it has higher wave angle. At night there is no
difference in noise, they are identical.

Noise comes from many directions, signals primarily from one
direction. When you focus the antenna, the total noise power drops at
a much faster rate than the signal. It is not necessary to have gain
to see this advantage, all you need is directivity.

>For a moment let us consider what the ideal would be supposing for a moment
>that it was possible. The real solution to your problem would be a highly
>directional antenna with no additional amplification because the AE would
>have a good efficiency and the signal would not be attenuated.

Directivity is a different parameter than gain. On 160 meters,
receiving antennas are typically designed with directivity in mind
since gain is easily made up for with amplification.

Most moderately or highly directional receiving antennas and most or
all physically small receiving antennas require amplification when
used with typical amateur radio receivers or transceivers.

S/N ratio has little to do with antenna gain, but antenna directivity
is extremely important.

>Try this for me. Insert an attenuator in the RX feed from your vertical and
>tell me if you get any better S/N. a thing that I try on 20 m some times
>when the band appears to be absolutely flat is to put 10 or 20 dB of
>attenuation into the Ae line and hey presto signals, not as many as usual
>but signals wher previously ther were none.

You have a receiver problem, unless you are using a direct conversion
receiver and accept the overload inherent in such simple designs. I
can't think of a receiver in common usage today that will suddenly
have signals appear on 20 meter when a 20dB attenuator is used!

Many receivers are somewhat marginal on gain or noise floor on higher bands even when used on large antennas, unless the site is particularly noisy.

If you have a receiver that generates broadband noise and needs extra filetering, and you don't have an exceptional situation where local broadcast or communications systems are extremely strong, you b need to repair or replace the receiver.

That is true ***ONLY*** if the shield is grounded at the correct spot,
that being the electrical center point of the shield, and if the
internal wires leave at that point.

If it is not grounded at the correct spot, and the internal
conductors do not exit the shield at that point, it will just as
easily make the situation worse.

Tom, W8JI wrote:
"You have neglected capacitance from the base of the antenna to the vehicle and the lead to the base of the antenna mount."

I am not sure, but Tom may be saying that a shielded/screened coil has less circulating current or more circulating current than the same coil as a segment of the vertical antenna.

If Tom is saying displacement current doesn`t affect radiation, he is correct if the displacement current is not in the phase and direction to aid or oppose the desired radiation. But, any radiation in an undesired direction takes radiation away from the desired direction.

If Tom is saying displacement current is a loser, where is the loss in the capacitance?

If Tom is saying current in an antenna-mounted loading coil that goes no farther than the loading coil has lost some of its promise as a radiation producer, that seems correct.

Terman says: "The first tower radiators were specifically designed to have a very small capacity from the lower end to ground, since it was assumed that this capacity was highly detrimental to the behavior. However, analysis shows that the ground capacity is harmful only if the ground losses in the immediate vicinity of the tower base are high, and the self-supporting type of structure is now generally accepted as being entirely suitable."

Current distribution makes the uniform cross-section tower more desirable for some purposes, but Terman was refering to loss. Self-supporting towers are accepted and many are in broadcast service.

HI Jason the Z-match on the DK-3 does just what you said. Except you do have to run the DK-3 up and down to adjust for the proper frequency. I am using a DK-3 on my Jeep Cherokee with an Icom 706 works great.

To answer your second question more people have copied Don's use of the Z-match and are using it on
screwdriver antennas now.

Remember the Z-match is for matching the antenna to the feedline not to tune the antenna to lenght.

4833. Non-Dissipative Resistance Revisited

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-13 20:03:11 UTC
From: Walter Maxwell <w2du@iag.net>
Message-ID: <q0vr6.27343$Ac5.6317822@e3500-chi1.usenetserver.com>
Source record: 168608

Sorry I missed the informative debate concerning non-dissipative resistance until now, but I would like to add the following info.

My 2nd edition of Reflections is about to go to print, and hopefully copies will be available at Dayton. I have included an Appendix dealing with this subject, and if I had been privy to the NG debate before finalizing the Appendix some of it would have worded differently, especially the more precise Newton definition of 'dissipation', in contrast to that of the IEEE.

However, in appreciation of Peter's revealing of the IEEE's error in causing the confusion over the definition, I quote a few lines from the first paragraph of my Appendix on the subject:

"The concept of a non-dissipative resistance is one of the most misunderstood concepts in all electrical engineering. There are at least two reasons for this misunderstanding. First, we learned about dissipative resistance while studying DC circuits, but when moving on to AC theory, many may have failed to notice that dissipative resistance is not the only kind of resistance. In addition, the concept was seldom, if ever, discussed by the EE professors. Second, the IEEE, in its infinite wisdom, chose to assign the same name, resistance, to both types, dissipative and non-dissipative, resulting in the present confusion."

Source record: 168609

The match is an inductor in parallel with the feed point. In combination with a slightly capacitive setting of the antenna, it acts as an L network to match the feed point to 50 ohms.

Even when the inductance is not QUITE right for a perfect match, a close match may be accomplished. On higher-frequency bands, the antenna impedance increases, making this match less necessary. In practical terms, if you use an inductance correct for (say) 75 meters, you will be able to get a good enough SWR on other, higher frequency bands. And this works for me with a Texas Bug Catcher.

Source record: 168519

I live in an apartment (ground floor) patio faces east 6'x8'
I can put anything I want on the rail or out on the patio I can setup
something in the grass but must take it in and out when not in use. I could
put anything up with a max height of 12'.

I am getting an kenwood ts-450 in the next week and I need an antenna that
will let me use it I really don't want to put up a different antenna for
each band. rig has a built in antenna tuner.

I am willing to buy or build an antenna

I just want what ever I put up to be good and work well.

so my question is what is the best antenna I can put up, build, buy?
I know I have to compromise a bit on signal quality but I will live with
that

4836. Re: balun vs swr

Newsgroup: rec.radio.amateur.antenna

Source record: 168610

I'm assuming you mean a 1:1 balun; otherwise you'll need a different load impedance.

Your test will tell you the SWR when the balun is presented with a 50 ohm balanced load. But you won't get any information at all about how well the balun is performing its intended function.

If you want to test a current balun for its ability to balance currents in worst case operation, connect the rig to one end through your SWR meter. Note that there's DC continuity through the balun, so conductor A at the input is carried through as conductor A at the output, and the same for conductor B. Call the conductor connected to your rig's coax shield conductor B. Connect the output conductor A to the input conductor B with as short a wire as possible. Connect your 50 ohms load between this junction and output conductor A. A good 1:1 current balun will show a reasonable SWR when connected this way. This represents a worst case imbalance, much worse than you're ever likely to see. A really good balun will pass this test. Some baluns that won't pass will still do an adequate job in a real application.

Don't do this test at your rig's full output power, in case the balun isn't doing a good job. And don't test voltage baluns this way -- a good voltage balun will present an RF short circuit at the input when connected like this.

Source record: 168611

Differently shaped or constructed antennas can have vastly different near field characteristics while having the same far field characteristics, or the other way around. A classic example is a small loop vs a short dipole. Measuring the near field wouldn't tell you much about how much energy is escaping to the far field, which is what you communicate with. So you can't use near field measurements to determine the relative far field strengths from different antennas (unless they and their surroundings are identical).

If you're comparing two different antennas and want to know how their far field strengths differ, you have to measure the far field strength. If you have one antenna and want to know the best setting for your tuner or which feedline has the least loss, you can measure either the near or far field and get the information you need.

Hi Walt,

Good to see you back and in the saddle.

As for coverage by EE professors. This was topic one of day one of EE
101 for me from a practical Engineer (from the local HP plant) serving
on the school's academic faculty. Only the academics (and we have one
doktor who never seems to quite "get it") demand these split hairs.

I would offer that the notion of "non-dissipative" resistance is like
a duck-billed platypus - except that "non-dissipative" resistance is a
barren invention of man.

What purpose does this distinction make? To answer that energy went
away without being rendered into heat (deceleration of charge)?

Saying so in so many words as above clearly does not cry for the
invention of a term and is far more understandable.

I would add that there are many more resistances that are discussed in
the trade that need no new vernacular. One bearing on this notion of
heat is found in "Thermal Resistance." It properly identifies
dissipation as the transfer of energy from source to sink and doesn't
need to prostitute language for the re-invention of a word to describe
what language already encompasses.

If everyone were to suddenly lose this expression ("dissipationless"),
the world would not collapse overnight, and in all likelihood, the
communication of what that corrupted term meant would probably occur
far more satisfactorily. This is because that communication would not

be fighting language and presenting paradoxes of half mumbled perversions of meaning to fit this term into a dialog.

Bill:

Interesting story, no surprise.

I would not waste my time or Chip's in complaining to Yahoo. I know why he wants to exclude me from the list, which is fine with me since its his list. I was simply interested in browsing the archives.

I think its a bit amusing that Phil and Chip keep announcing the QST to "all interested hams" but the list moderator (chip) ultimately excludes those whose opinions differ from his. In announcing the QST, they should stipulate that it is not an open forum and that it is heavily moderated and filtered to exclude opinions that differ from Chip's (at least that's the way it appears).

I also think that this recent surge of Phil posts is timed with the n1ir.com web page, soon to come on line.

That's why they call these things threads - they may wander off in any
direction. What I'm wondering is why we go to great lengths to measure
only far fields in the mobile antenna shootouts while you are satisfied
with measureing the near field under your antenna. I am trying to learn
something from this thread. There's no criticism implied. If an FSM close
to the antenna is sufficient, why don't we do that for the mobile shootouts?

My question is: Exactly what is that consideration? If an FSM in the
near field under an antenna is sufficient, why do we go to such great
lengths to measure only the far fields during a mobile shootout?

You are welcome. Sorry I made a mistake. I wrote: "Lambda = Wavelength in meters per second". That would be a velocity, so the "per second" should be deleted.

Wavelength is the distance traveled by a wave in the time of one cycle, but it is just a distance.
The higher the frequency, the shorter the distance traveled during one cycle.

A good troll gets people upset enough to respond. A great one gets
complaints to various organizations and federal agencies.

I see the threads' title as L Tuner Adjustments, that is what I had
originally comment on and am know. I said nothing about shoot outs,
antenna near fields nor antenna far fields. I had said that using a FS
for antenna turner adjustments was, in my opinion, the best way.

SK on the subject.

Two meter repeaters are not representative of most hams - especially in any
major city. Try working some two meter SSB, or better yet, spend some time
on HF. You will find a completely different type of operator.

You might go to the ARRL site -- http://www.arrl.org

Look in the ARRL book section. They have a number of books devoted to stealth antennas -- as well as limited-space antennas. You're going to have to be inventive, working from a ground floor apartment, and these books will give you a lot of ideas.

A couple of commercial ideas -- go to http://www.hsantennas.com//index.html and look at their screwdriver antenna with their ground-level Tripod Mount.

Or go to http://www.bwantennas.com/ and look at their portable AP-10A window-mount antenna. I used one from an apartment (3rd story) and got out well.

Good luck!

Tom W8JI wrote -

> Unless something in
> the system is poorly designed, the shield does nothing at all.
==========

Very true. Small loops in most envirinments don't need any
shielding. They are inherently so insensitive to the electric field
relative to the magnetic field, shielding offers no advantages.
Unfortunately, radio periodical publishers and editors don't have
space for dreary, un-interesting articles about simple, unscreened
receiving loops.

As a result, it seldom occurs to fresh, young experimenters to make
a recieving loop without a shield. They are beguiled to form loops
from such materials as the inner conductors of coax cable which are
much less efficient than loops formed from the outer conductors of
the same size cables.

==========
> and loops have
> real SHARP nulls when properly balanced and shielded!).
==========

But so does a short horizontal dipole. The radiating/receiving
patterns are identical except for a 90 degrees rotation. And a
horizontal dipole is insensitive to vertically polarised noise, the
most common sort.

>161.45 MHz.

Thank you for that reminder. Since I don't own an SWR meter, is it
possible to tune the antenna by just measuring the current to the
tranceiever during tx (its actually a 12-V set) and trimming the
antenna for a peaking of the 12V current? Are there
other ways of checking for resonance of antennae?

I think like a land-lubber. Of course it helps next to the sea,
because that is your terrain!

I couldn't resist making that comment because my neighbor always
insists he gets out well on HF because he is 950 feet ASL. Since the
sea is 250 miles east, that really doesn't matter.

The extreme of that is you can simply measure current into the
feedpoint, or voltage, and tune the tuner for maximum.

When the antenna is unchanged, you can measure FS anywhere and get a
good answer.

BTW, even 1 wl is plenty for your shootouts. I certainly wouldn't
worry about being out ten.

The exception would be if some clown brings a mobile antenna a few
wavelengths long.

I want to mount my screwdriver antenna on my 94 buick century. I would like to mount it on the bumper, but can't see screwing up the vynal (/) / plastic permantly on the thing. Has anyone cut holes for a ball mount in the side rear quarterpanel and was it (the aluminum panel) sufficient to support the antenna without overstressing the car's quarterpanal? Trunk mount with ball into the trunk top or bottm near the keyhole? My other car was no sweat for mounting hada trailer mt.

Dealers want a fortune to install a trailer hitch, Ryder's quote was near 300.00 tooooooo much!

>as a segment of the vertical antenna.

The capacitance of the antenna base to chassis, and capaciatnce of the lead to the inductor to the chassis, and the inductor (past the winding start) to the chassis all increase the current in the inductor without contributing radiation.

Loss increases from that unnecessary current.

The antenna itself and ground system have no change in loss, only the inductor. That change is significant.

The neat thing is if you measure the input resistance of the antenna system it can actually drop as losses increase.

: > particularly if you have been warned.

: Consider the patent application process. A person applies for a patent.
: The application contains a handful of claims which describe precisely
: what combination the patent is to cover. The patent examiner throws out
: a bunch of the claims, says others are too broad, and sends it back. The
: applicant re-writes the patent to try to satisfy the examiner, and so
: forth. This can go on for literally years. The result is frequently a
: patent that hardly resembles the original, and often no patent at all.
:

I've been very fortunate with all of mine, so far. Of the two
that have been issued, the one that is now allowed, and the one that I'm
still prosecuting, I have managed to get all of my claims. I've had to
rewrite a number of them because they were not descriptive enough as
originally filed to be patentable over prior art, but by working with the
examiners (provided that they understand that pro se applicants are
entitled to constructive assistance by law) and being fortunate to have
a patent attorney who helps me on a consultation basis, the problems are
ironed out very quickly.

I have had to combine two claims as one a couple of times in order
to make a basis claim stand on it's own, but that still counts as having
all claims granted. Before this year is over, I will have six in all and
there are three more yet to come.

==========
Being inside the near field is not of great consequence when the parameter of interest is the received signal strength for a given Tx power. Provided, of course, the Tx to Rx distance is the same for all measurements it doesn't matter what the distance is. The near and far fields vary precisely in sympathy with each other. They are just two different ways of looking at one common field. The parameter being measured and compared is a simple ratio - radiating efficiency.

Taking the risk of bringing retribution down upon myself, I think a more accurate way of comparing radiating efficiencies would be to bring a simple hand-held field-strength measuring instrument well inside the near field. Then walk all round the antenna under test at a constant distance from it and take the average reading. Absolute accuracy of the meter is irrelevant since our intention is merely to compare one antenna with another. But no self-respecting amateur would accept this as a genuine shoot-out.

Do you use an external antenna on your field strength meter or the short whip on the meter? If the short whip on the meter, and in the shack, could there
be false readings by stray rf in the shack? I have considered using a field strength
meter but have not as of yet. (don't know why)

Hi Butch,

I have my screwdriver mounted 33" off the ground on a "L" bracket we formed with "L" stock. with a welded brace to keep shaking to a minimum. It's mounted to the frame with ONE bolt and has not required ANY maintenance what so ever in over half a year AND that includes running into the garage without quick disconnecting the stinger (a definite no-no). The mount over runs the bolt, so limiting all rotational movement past vertical. Also easy off!

I gave contesters and Dxers a challenge to build a G4ZU Birdcage for either 80 or 160 a couple of years ago. I don't know of anyone who has one, but I do know that many are looking for
a way to improve their signal over a four square or even a set of K8UR vertical dipoles. The G4ZU birdcage (see CQ Magazine
April 1960) is a 2 el quad folded back on itself G4ZU found that using just a portion of the birdcage (the bottom X) gave
almost the same results. He labeled this the X beam. Moxon G6XN noted the defect with the X beam was spurious radiation off the
sides. W9PNE used wireback wires to cut these side emissions (See the ARRL Antenna Compendium Vol 1). There was an excellent article in a 1991 73 magazine, too.

I have used the X beam with wirebacks on 12 meters for 6 years and have worked 306 DXCC countries. W9PNE says it performs like a 3 el beam on the design band, but its only a 2 el beam with driven element and director (very close spacing) so I feel that it has or approaches 5DBd of a 2 el beam. It does compete with the A3WS and similar beams. This could be adapted to 80 meters and since it has NO BOOM (it appears as a 64+ foot X) this appears to have reasonable probability of giving one a 5Dbd directional beam on 80. It has fairly wide 2 to 1 swr footprint but would probably require relays to switch
between CW and SSB (3505 and 3795).

This beats or exceeds most of the short beams on 80 and would be a lot less trouble to maintain. On 12 I have 10 to 15 DB front to back
and 25DB front to side with sharp nulls at several points. It is 5.5 feet below my KT34XA and does not seem to interact. I would guess
it would need to be 10 feet or more away from a 40 meter beam.

Any takers? If I can find the right materials I would put one on my tower but its at a max now.

4875. FRACTAL ANTENNAS At IEEE APS in July

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-14 03:23:20 UTC
From: fractenna@aol.com
Message-ID: <20010313222320.02067.00001270@ng-cu1.aol.com>
Source record: 168550

Boston will be the scene for some fun fractal doin's in July. In addition to a special session on fractal antennas, Dr. Doug Werner will be giving a short course on fractal antennas. (There will be some very interesting 'fractal' surprises at the meeting also. Boston is the home turf of Fractal Antenna Systems, Inc.)

Here's a description from the web page

http://www.ewh.ieee.org/soc/aps/2001/workshop/WorkshopShort.htm

---

FRACTAL ANTENNAS SHORT COURSE

Course Outline: Fractal electrodynamics is a relatively new and rapidly growing field of research that deals with combining attributes of fractal geometry with Maxwell’s theory of electromagnetism. One of the newest areas of fractal electrodynamics research concerns its application to antenna engineering, which promises to yield a rich class of new designs for multiband antenna elements as well as arrays (D.H. Werner and R. Mittra, Frontiers in Electromagnetics, IEEE Press, 2000). This short course will present an overview of research in the area of fractal antennas. Recent advancements in the fundamental theory and associated design methodologies for fractal antennas will also be discussed.

Various fractal design schemes will be considered for antenna elements that, due to self-similarity in their geometrical structure, have a multiplicity of resonances over some predetermined operating bandwidth. In other words, these fractal antenna elements exhibit multiband or, in some cases, even broadband behavior which is directly linked to the fact that their main geometrical feature is repeated at many different scales within the structure. Innovative techniques for developing compact low-profile antenna elements using fractal geometric concepts will also be discussed.

Another topic that will be addressed in this short course concerns the use of fractal concepts in the design of antenna arrays. Fractal arrays offer several attractive advantages over conventional array designs including multiband/broadband properties, the availability of recursive algorithms for rapid radiation pattern computations, schemes for realizing practical low sidelobe designs, systematic approaches to thinning, and efficient design strategies for large planar arrays. Finally, the design of multiband fractal frequency selective surfaces will also be briefly discussed.

Fractal element antennas are patent and patent pending by Fractal Antenna Systems, Inc.

Source record: 168551

Look in some of the ARRL books for the standard gain antenna for the standard gain antenna. It is for 432 mhz, but you should be able to scale it for 800 mhz. It is something like a 1/2 wave dipole over a reflector/ground plane that is 1 wavelength square. They say it is from the National Burau of Standards, now called something else. It is for 7.7 db over an isotropic antenna and should be reproduciable to within about .25 db.

>near field under an antenna is sufficient, why do we go to such great
>lengths to measure only the far fields during a mobile shootout?

Hi Cecil,

That is a very simple question which has a very simple answer.

Variation.

In other words, there is some variation as each contestant "comes onto
the field" so to speak. If this were your shack with the FSM nearby,
you would always be making the same measurement - this may not be the
case in the shootout (the antenna configurations do vary, that's the
point of the shoot out isn't it?). And

However, as all antennas are extremely short - by enforcement - I
would allow that each and every near/far field is identical in
geometry if not amplitude. Thus this first consideration of variation
does not seem to account for much.

But the simple answer still stands with a simpler application. Each
mobile unit moves and by moving does not occupy the same place the
last unit did. Well, maybe you tried your best to hold that variable
down. If you did, you were conscious of the possible effects of one
unit being closer than another. Here, distance is your friend in that
if the FSM were a hundred feet away, you would have to hold the
radiator to one place +/- 1 foot for 1% accuracy. By moving out to
1000 feet, the variation of 1 foot is lost in the noise.

By moving out a greater distance, you can allow for more tolerance in
just what constitutes the shoot-out point of radiation. I noted that
some rigs had directionality that was observed as they turned during
transmission. If you were too close, this could have been an artifact
of variation in distance rather than radiator efficiency.

This last variation still constitutes a small percentage of error, but
is far more prone to becoming the loss leader if neglected (like my
observation of the turning unit). It has a very simple resolution:

move out further! This is cheap accuracy - you don't get many chances to shave points.

The simple resolution is not without simple problems tho'. Measuring a weaker signal is not the problem. You already bought into that cost by measuring remotely. No, more the problem is multipath where reflected signals will compete at possible greater ratios than closer in where the original signal can swamp artifacts of reflection. This may not be such a problem given that all contestants will suffer equally - except for those same units that exhibited directionality.

As for these sources of reflection, you might want to consider every contestant and that field is changing with every measurement. Are they out 10 wavelength's? There is no point in these tuned elements being anywhere near the source nor the FSM.

As a variation to your practice, Cecil, you might as well put out three FSM's, radially, at 2 waves, 5 waves, 10 waves or some variation to suit the occassion. This is insurance against the odd failure or other examples from hyper-gain inventors. Call it fractsurance. You could even pull those FSM's in to .25 wave, .5 wave, 1 wave. IFFF you can assure that what you call the radiation source is located at a specific point within the limits of accuracy you desire - n'est pas?

As for accuracy....

Butch,

Look up under the bumper. There *should* be a piece that runs across the car sort of like angle iron (L-shaped with the "lip" of the "L" towards the front. There also may be some holes at various points across this piece. I have a Lumina and I was able to mount my bracket straight out from under the plactic fascia at an existing hole. This also allowed me to brace the screwdriver right under the trunk lid. I am thinking the Century *may* be similar to the Lumina. If you choose this location, you may have to re-inforce that cross piece and add a brace to another place on the same metal. This is to reduce shaking as the L piece is rather light weight and will jiggle if not braced.

If you decide to body mount the thing with a ball, I should think the sheet metal won't be heavy enough by itself. Go to a metal recycling yard and get some 1/8" metal somewhat larger than the base of the ball mount. Use the template to cut out the holes. Put this plate inside the fender and mount to this thru the body. This will spread the load out and make for a secure mount.

Not sure how to mount a screwdriver on the rear deck of a car. Screw-drivers are HEAVY, and present a good deal of wind load. You've only got that little 3/8" stud holding it (if it is mounted like most of 'em) and you're sure to need some kind of solid brace about halfway up the mast. Same if it's on the fender. On the deck, there's nowhere to attach this brace. (drill holes in the roof? YIKES!)

Good luck and hope this helps.

You're just trying to get the maximum power out of the tuner. If you have common mode problems doesn't take away from the fact that when you tune for maximum smoke (maximum reading on the FS) you've adjusted the tuner about as good as you're going to do. There are no false readings maximum out is maximum out.

Sure you will, W6DKN. Have you been to 3.860 MHz lately? The two-meter operators are not any better or worse than any other ham. I take that back, at least the two-meter operators don't usually go around promoting bigotry towards their fellow hams.

On my car I have the antenna mounted on the trunk lid. About a foot or
so behind the back window, or maybe 6 inches or so back from the front
facing trunk lip. What I had to do was get a big circular plate of real
heavy steel and place it under the trunk metal on the inside. I was able
to squeeze it in flush with the trunk metal.
This spreads the load out quite a bit. Also I have wood spacers also
pressed in between the top trunk metal, and the inside "framing" which
they add to make the trunk stronger. This keeps the plate from being
able to flex the trunk lid. I use a hustler quick disconnect as the
stub. I don't know if it would handle a screwdriver, but most likely I
think it would as long as you didn't get carried away with the weight.
I've used that mount quite a long time and have never had any trouble.
Works good rf wise too. I think it helps to have the metal under the
antenna. MK

I'll assume that you hold a General class license or higher.

Get a small antenna tripod, a small piece of antenna masting
and a used Solarcon A-99 fibreglass CB antenna (or
equivalent).

This combination will get you on 17, 21, 24 and 10 meters
just using the auto tuner in your Kenwood TM-450/AT and can
be disassembled and stored in just a couple of minutes. Not
to mention that it is very inexpensive.

Oh, it will stand about 20' high, but others will think that
you are getting ready to go fishing. 8>)

Nature, not man, dictates that when you put 50 volts on an almost endless transmission line, 1 ampere flows. Man used nature`s laws to make coax that has that exact voltage to current ratio, but man can`t make the laws of nature. Man can`t even break the laws of nature.

How bout a lightweight thin wire hat? Of course, you would need
something to tie them off to, kinda guy wires on a tower, but they would
support the whip the same as guys. I guess you could even use a single
wire , ala inv L. You would want to keep the downward slope to a minumum
I would think. MK

You may recall several years ago when the FCC did a power survey of several ham radio stations where they actually went to hams' homes, had them put a high power signal on the air, around a KW, then drop the power down to 100 watts. Much to the surprise of all involved, very little difference was found in the level of RFI to consumer devices between a KW and 100 watts. I always believed that the survey would have resulted in decreased maximum power limits for hams had it shown a significant increase om problems caused by running high power.
This was reported in some of the ham press. One of the areas where the testing was dome was Kansas City.
And yes indeed, there are great differences in receiver responses to off- frequency signals. I still recall when I had an original Kenwood TS520, hearing a ham who lived a half mile from me and DID run a SB220 on SSB, and I could hear him several places on the 20 meter band simultaneously. Not his fault, but rather the fairly poor strong signal handling capabilities of the original TS520's reciever. Later versions improved considerably.

Yes the cable system usually disconnects the connection in theory. But after
20
years in the cable biz I know there are many lazy employees who prefer to do
the

disconnects on paper rather than climbing the pole or putting up the ladder.

Then there are the employees who do put up the ladder but disconnect in
error
the neighbors house. Most of the time the loose end is screwed into special
terminator that locks the port on the subscriber tap to prevent theft of
service. All in all this is a terrible idea and should not be attempted.
What is

to say one day you are transmitting away unaware that a employee is climbing

that pole to connect someones service other than yours and he grabs the end
of
your unauthorized connection while transmitting 100 watts and he is thrown
off
the pole with a nasty RF burn. If he lives through the fall. I would come up
to
your apartment with my climbing gear on and climb up and down your back. I
have
been a ham for 30 years and in the cable biz for 20....Do not attempt that
foolish maneuver... IMHO....K7FU

So, if you know where the jerks are, why waste your time there? At least they occupy a small, known piece of the band so the trash is easy to avoid - unless you're the type that likes this stuff. (Yes, I have heard about the crap on 3.860, but I have no desire to waste my time with it)

Personally I prefer to work DX and do very little stateside work (which seems to be where most of the problem operators are on HF). I work 12, 17, 20, and 40 almost every day and I have never had anything but great QSO's. I do work VHF/UHF also, but I only do SSB or FM simplex and SATS. There are very few "garbage operators" in these modes.

At least on HF, the jerks stay in a small, relatively consistent spot and it is fairly common knowledge where they are, so they are very easy to avoid. Very different than the VHF repeaters in the big cities, where the jerks get their kicks from going from machine to machine to see what trouble they can cause (just like 11 meters).

4896. SKY TEMPERATURE FOR HAMS

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-14 08:19:59 UTC

Message-ID: <98n9gabgg1@lure.pipex.net>
Source record: 168470

It has long been a pain for me to find a simple reference that can be used by Hams to calculate the thresholds that they may expect upon each band when the receiver is connected to an antenna.
Her I have produced this important work a precis and translation of the theoretical and experimental work of David Hogg and W W Mumford of Bell Labs into a form readily useable by Hams, I know that most Hams have few if any Mathematical skills, and thsoe that do attempt a few elementary calculations are often unsure of their results. I hope that this posting will fill one gap for many.
The text and the calculations are my original work and I accept the responsibilty for any errors found.

SKY TEMPERATURE FOR HAMS
Sky Temperature Hogg and Mumford

frequency| Tsky | Min Tsky | Max Tsky | Tsun
136 kHz| 3.67E+09 K| 2.82E+08 K| 7.06E+09 K|4.96E+06 K

434 MHz| 360 K| 28 K| 693 K| 1,555 K

The first work on Sky Temperature was by Jansky,
this work was followed by
Cottony & Johler; Brown & Hazard; and a whole string of investigators.

Hogg & Mumford produced a paper for Bell Telephone Laboratories, Whippany New Jersey.

"The Effective Noise Temperature of the Sky"

In this paper they propose a formula that nearly describes the Sky Temperature Noise as a function of frequency.

Their work was checked by a number of independent investigators and observed sky noise temperatures showed close agreement to the predicted values.

Whilst reading their paper I felt that their more exact formulae could be modified to produce some simple rule of thumb work horse that many Hams would be able to use in their day to day experimentation.

As there is a variation of Sky Noise Temperature the upper and lower limits to be expected are given by the formulae:

Max Tsky = (1.305 x 10^20) / f^2

Min Tsky = (5.22 x 10^18) / f^2

You will note that there is approximately 14 dB spread between the upper and lower Sky Temperatures.

In order to avoid calculating every time that you want to have an idea of the noise temperature within a particular Ham Band refer to the table above.

For completeness I have added a column for the noise temperature of the Sun. As you will see at the low frequencies the Sun is not a great contributor to Sky Temperature and it is directional on the higher frequencies. The temperature given for Tsun is what would be seen by an antenna with 0.5 degree beam-width pointed directly at the sun. In order to adjust the Sun Temperature to your particular antenna you must divide the given temperature by: 4 x beam-width squared.

Sun Temperature is about equal to Galactic Sky Temperature at around 2 m and predominates at 70 cm, so keep that AE pointing away from the Sun for best S/N ratios and thresholds on this and bands above.

Most of the Sky Temperature is of Galactic origin and there is an increase when looking directly at the galactic centre.
With the sorts of antenna commonly encountered amongst Hams this effect will be minimal because of the wide beam widths of HF antennae. At VHF the effect will begin to become noticeable.

Straight line graphs result if this table is plotted on Log Log graph paper. You may therefore take the upper and lower point for each column plot them and join with a straight line.

At the lower HF frequencies local and distant lightening will increase the Sky Temperature occassionally, but you will notice a difference in the character of the noise sound, there are distinct pops and bangs producing noise peaks as well as an increase in the average Sky Noise Temperature.

The graph in the "RSGB Communications Handbook" Fig 15.6 is pretty well spot on. However it would be useful to see the vertical scale also calibrated in temperature.

I really must protest at that statement, if ther has been any incorrect data then I presume that you will be claiming responsibility for it. I bend over backwards to be truthful and accurate, I never knowingly and deliberately propagate rubbish, dealing with the truth in this world is a full time job without wasting time on spurious nonsense.

>They also ignored noise reduction by
> directivity, and considered the receiver much more sensitive than most
> are.

I think that I qualified my statements as a generality and as such the calculations define the absolute best conditions that may be expected. See another posting by me just released in this news group. Your quite correct jib that I should not rely upon an illustration if a Ham publication for my authority I have traced the source, (looked back into my old files), and clarified the Sky Noise Temperature for All Ham Bands from 136 kHz to 434 MHz in tabular form showing maximum and minimum Sky Temperatures for each band. Thank you for prompting me to finally get off my fat arse and do something about it.

If it has nothing to do with it then why go to such lengths to acheive a directional receiving antenna if it will make no difference?

> The directivity of a small loop is such that it is mainly vertically
> polarized, so polarization is also not an issue.

I think a search of the literature will not substantiate that statement.

> The small loop does
> not have significantly more directivity that the vertical, but it will
> allow us to null noise from a single direction (or two if you are very
> lucky and they are about 180 degrees apart).

Surly the abilty to null implies directivity,
your statement is a blatent contradiction.

> The only reason a small antenna is better is because it can be moved
> away from a very local noise source, and can be used to null a local
> noise source.

When you say that it can be moved away, do you mean that it may be rotated
or that it is physicaly repositioned at another place?
If you mean that it is rotated then you are relying upon the directivity of
the antenna to position a local noise source into a null.

> tropical regions.

I suggest that you take a trip to VK and listen during the week and at the
week end with your beam pointing into Europe. As somebody that like
empirical work this exercise should apeal to you. I have done it, the effect
is quite noticable.

> QRM is normally not defined as "noise". Noise is normally considered
> to be random broadband interference.

That good buddy is QRN

N for Natural
M for Man made
both are defined as noise though differewnt in character they are both
random and both degrade the threshold of a receiving system.

>What we hear on 160 meters is a
> collection of many noise sources, most of which are arcs and sparks
> either in nature of man-made devices.

The background noise is Galactic noise peaking slightly towards the galactic
centre.
Superimposed upon this in our modern world is the arcs and sparks of
civilistation. another reason that top band is generally a rich man's sport.
Those of use condemned to the urban environment work between the noise
bursts. Attempting original work on sky temperature measurements is as much
an art as a science taking readings between the neighbours thermostat. I do
do quite a bit of that, however my AE efficiency at the lower frequencies is

in sufficient for results that satisfy me. By taking a large number of readings of a long time period (years) and comparing these to the accepted values for sky temperature it is possible to calibrate the AE efficiency and then normalise the results retrospectively. Not recomended unless like me you are totally obsessed by getting a result. ;)

That is interesting have you attempted making a radio noise map?
That would be a significant and interesting contribution, especially if you can get it independently verified. Which bands have you done this most interesting work on?

I am sorry to keep labouring the point but I prefer to take the word of the established scientific community in this respect they tear one another to pieces in an endevour to reach the truth. If your measurements are consistently returning much lower temperatures then I suggest that you have not taken your Antenna efficiency into account. None will be 100% efficient. If you divide the values that you measure by the values from my table in another post in this news group you will derive the correct antenna efficiency figures for your antenna This will be very useful information as you will then have some idea of just how much you might expect to be able to improve the efficiency and you will also be able to calibrate the actual received signal levels in free space around your AE.

> >Yes indeed yopu have verified just how noisy verticals are, you will never

Ah! do I detect a chink in your armour?
Incidentally how do you focus your AE on 160 m?

> >For a moment let us consider what the ideal would be supposing for a
moment
> >that it was possible. The real solution to your problem would be a highly
> >directional antenna with no additional amplification because the AE would
> >have a good efficiency and the signal would not be attenuated.
>
> Directivity is a different parameter than gain.

Quite so, directivity is a reduction from unity gain in all directions other than the direction desired for optimum reception of a signal. It is of course this factor that improves the signal to noise ratio without actuall receiving a stronger signal. the improvement is all due to noise reduction. This effect was most noticable when taking the very first Lunar Surface poictures from Surveyor III. during the flight the spacecraft signal was viewed by an antenna with 0.3 degres beam width mainly illuminated by the background sky noise of 4�K.
Once the space craft had soft landed the aperature of the antenna was completly filled by the disc of the Moon 0.5 degree diameter at a temperature of 150�K (I made the first measurement of this phenomenon. It was neccassary to command the spacecraft signal off in order to make the measurement. The additional noise came as a bit of a surprise to the analysis team it was afctor that had not been considered at the planning stage. Fortunately I was able to design a high sided filter to restore 3 dB of signal to noise but obviously I could not reclaim the 15.7 dB loss without an increase in the transmitter power of the spacecraft or antenna gain. This power and antenna size limit are set by rocket launch considerations, (bigger transmitter, bigger solar array, more fuel to carry it more fuel to carry the extra fuel and the bigger tank to carry it etc amount to a factor of 19, (i.e. add a lb to the weight of the payload means adding 19 lbs to the launch weight), multiply that out by the distance and escape velocity required then ten Watts on board becomes a practical launch restraint).
Thus any of the Surveyor Pictures including Rock 'A' per the scientific magazine 'Nature' have a signal to noise ratio of about 13 dB, not very good

for imaging, but for a world first bloody excellent. I can still remember
the stunned faces when the bird actually got down safely, I can still see
the spacecraft pilot risng on his stool as he guided it down to the surface,
I swear that by the time that it touched down Frank was levitating. A pause
ensued and then the question from the team leader, " well what shall we do
now, take some pictures I suppose." Thus started an intensive session where
10,000 polaroid images of the slow scan TV were taken the whole were then
trimmed and mounted on the wall above the stairs coming into the tracking
station, one huge panoramic image of the Moon's surface about 15 feet
across. 13 dB S/N
But I digress, silly old fart, The point that I am trying to make is that
you can not improve upon the S/N Ratio that comes into your AE, every thing
that you do from then on degrades that S/N Ratio.

>On 160 meters,
> receiving antennas are typically designed with directivity in mind
> since gain is easily made up for with amplification.

Gain is merely attempting to bring the low siganl level from an inefficient
antenna up to the levels normally used by the commonly available Ham
communications receiver. I would expect thes considerably less than a
wavelength AEs to be inefficient, wouldn't you?

> Most moderately or highly directional receiving antennas and most or
> all physically small receiving antennas require amplification when
> used with typical amateur radio receivers or transceivers.

To over come their inefficiency, however using this technique does not
acheive the S/N that is present in the space surrounding the AE.

> S/N ratio has little to do with antenna gain, but antenna directivity
> is extremely important.

I suppose if your antenna is already so inefficient then anything that you
can do with the attenuated signal will appear to be an improvement in S/N.
The improvement that you are observing is raising the small signal above the
noise figure threshold of the receiver that is being used.

> >Try this for me. Insert an attenuator in the RX feed from your vertical

Well unfortunately for you this effect will be observed on any number of
receivers of the black box variety because the front ends are wide open.

There is no fault on my Rx (Kenwood R-5000 and R-1000, others various including valve sets)
You will have to wait for a high noise day to observe this effect.

> bands even when used on large antennas, unless the site is
> particularly noisy.

Not a problem with any of my Rx, apart from those that are untouched to manufactures specs I do calibrate my receivers before commisioning them. I don't use them much for collecting bus numbers my interests are mainly scientific. I get more kick from measuring the sky temperature than scoring rare DX. Too many other factors such as when the op goes to bed or work figure in the serendipitous reception of DX. The transmitting stations are mainly uncalibrated or not calibrated to an accuracy for my purposes. I would like to see a big improvement in this direction by all Hams in order that short term and long term variations in propagation might be studied more carefully.

I'm sorry if I want to generate broad band noise I use a noise source, which at best will produce pink noise not the white variety that I would prefer.

Do try to get a grasp of Noise Temperature it will enhance your understanding of the subject.

Hi Richard et al. my remarks are despite the appearance otherwise are not anti American.
There seems to be something; lacking in the training of the American Serviceman when you consider the number of friendly fire incidents; particularly as this is the second time that US troops have wiped out a number of Kiwis.
It is important not to kill your own troops, but more so not to kill your allies.
One can understand the pressure on the individual in a battle situation or the hot pursuit of an exercise however I suggest that there is an element missing from the training and culture of American troops considering the now quite large number of such incidents. Any one that has done time in the military will have witnessed the gung ho of certain individuals, there is probably a place for that, but it must be disciplined and controlled.
If your friends can't tell you that you have BO, who can? :)

It was nice to see the naming of USS WS Churchill, of course many will not know or have forgotten that VVinnie had an American Mum, (sorry, Mom), and as such probably had residential rights in the US.
I am sure that we will continue to work together despite this recent unfortunate incident. Hopefully it will precipitate a review at the very least of training and discipline amongst the US forces. Of course there will be further incidents statistically they are impossible to avoid completely, however in Vietnam certain of the allied troops did not wish to fight with the Americans because of their indiscipline, and going on patrol high on drugs and transistor radios blaring out in the hostile jungles. (That is from the horse's mouth, not newspaper reports or enemy propaganda.)

I suppose the polite thing is to not comment and ignore the problem, but that would be not only cowardly but irresponsible, it was the silence of the good people that permitted such excesses as NAZI Germany 1920 -1945, not that I am comparing this incident to such deliberate mal-practice. The fault if any is the laid back attitude of the American military culture. Firing from the hip seems to be the accepted practice. Clint Eastwood has a lot to answer for. (BTW I am an Eastwood Fan, so perhaps The Duke contributed too:)

Please ignore Reg's editing of what I actually posted, it annoys me, but in this medium there is little that can be done about it. He does get a bit OTT once he climbs onto his partisan soap box. You can detect the stilted phraseology, hopefully so can many others.

The references to 1942 are due to remarks of gratitude by me made in another news group.

That thought had not eluded me, however the gauge remains pegged when the
ignition is switched off and thus power is removed from the instrumentation.

The point is that the 2-meter versus HF operator nonsense you mentioned earlier has absolutely nothing to do with it - the "jerks" are the same on both (the only difference between 2-meters and HF is the limited number of repeaters on 2-meters - harder to avoid the "jerks" if you stay mainly on the repeaters).

Therefore, you should not have said earlier that the "two meter repeaters are not representative of most hams" (you said "hams" here) and that he should "spend some time on HF" because he "will find a completely different type of operator." That is not true. There are no more "jerks" on 2 meters than on HF - they're only a little more difficult to avoid because of the limited number of repeaters.

If the "jerks" really disturb you, then I agree with your suggestion - simply avoid the repeaters. Its far easier to avoid them on the SSB frequencies (just like on HF).

Take care, W6DKN.

Actually, I worded that reply wrong, Tom as it could appear as if I was baiting you. I should have queried differently - instead of "concern with height" perhaps along the lines of "Any interest in less concern with height."

I read often of folks elevating their verticals as high as possible because of the lousy soil conditions they face. Since I'm close to and on top of moist soil and water, can I be less concerned with the height of the antenna? Regards, Jim R.

I think like a land-lubber. Of course it helps next to the sea, because that is your terrain!

I couldn't resist making that comment because my neighbor always insists he gets out well on HF because he is 950 feet ASL. Since the sea is 250 miles east, that really doesn't matter.

Lets take a survey of the number of jerks and lids out of 1000 QSO's on the
2 meter repeaters in Los Angeles, and do the same with 1000 HF QSO's on 17
meters. If you are correct, the ratios should be about the same...

It has certainly been my experience over the last several years in/around the Los Angeles area of So CA. Maybe in your area things are different. But, like most people, we base our opinions on our personal experiences.

And let's not forget that my original response was to a post stating that from listening to 2 meters, the poster concluded that ham radio in general was just like 11 meters.

> If the "jerks" really disturb you, then I agree with your suggestion -
> simply avoid the repeaters. Its far easier to avoid them on the SSB

They don't disturb me - in fact they have no effect on me one way or the other - because I choose not to pay any attention to them.

Hi Richard,
an infinite, or even an almost infinite transmission
line, is an abstraction. Real transmission lines, of any sort,
have losses that would make them unsuitable for demonstrating the
non-dissipative resistance effect if their length was made infinite,
because any infinite length of transmission line with an
attenuation constant greater than zero would have infinite
attenuation over its length as well. Your conclusion is correct,
however, humans can't break natural laws. The trick is to find
out what they are and how they apply to the real world.

>point of the shoot out isn't it?). And

Hi Richard.

The antennas are less than 15 feet tall.

The distance to the measurement point is maybe 2500 feet, and is much greater than 1 wl, where field impedances settle down on small antennas.

The sense antenna is certainly much smaller than the test antennas.

The antennas are all basically the same configuration.

There is absolutely no way a sense antenna with these physical and electrical limits would "know" the induction field geometry of the antenna being tested changed.

They are well beyond the distance they need be at to make these measurements. Even 1 wl out would be acceptable with small antennas in the most critical appplications.

The certainly can hold physical errors within a much tighter tolerance than the measurement instrument errors.

Cecil, what they do is perfectly fine.

4912. Re: SKY TEMPERATURE FOR HAMS

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-14 15:58:18 UTC
From: 2w8ji@akorn.net
Message-ID: <3aaf8d27.175228926@news.accessunited.com>
Source record: 168481

Hi Gary,

Only an very inexperience beginner would think local noise is originated in space on HF bands, with the possible exception of bands above 20 meters at night or times when the ionosphere is so thin as to have little effect on signals.

Galactic temperature is virtually meaningless over all of HF, and certainly should never be used on bands below 10 MHz unless there are extreme exception to the normal application.

On Wed, 14 Mar 2001 08:19:59 -0000, "Gary Peach" <xcg34@dial.pipex.com> wrote:

>The text and the calculations are my original work and I accept the
>responsibilty for any errors found.

OK, that's good enough for me.

<SNIP>

>Most of the Sky Temperature is of Galactic origin and there is an increase
>when looking directly at the galactic centre.
>With the sorts of antenna commonly encountered amongst Hams this effect will
>be minimal because of the wide beam widths of HF antennae. At VHF the effect
>will begin to become noticeable.

Even with a narrow beamwidth antenna, galactic temperature is meaningless at HF and lower. The ionosphere acts like a shield or attenuator, and also conveys distant terrestrial noise sources, both man-made and by nature, to the antenna. By far this is the dominant source of noise where the ionosphere plays a role in propagation.

>At the lower HF frequencies local and distant lightening will increase the
>Sky Temperature occassionally, but you will notice a difference in the
>character of the noise sound, there are distinct pops and bangs producing
>noise peaks as well as an increase in the average Sky Noise Temperature.

You will NOT notice a difference in the "noise sound" because you will virtually never be able to hear galactic noise below 15 MHz on any antenna system at any time. It will be attenuated by the ionosphere to the point where its level is lower than propagated terrestrial noises, which often also sound "white" because the noise is from many thousands of random sources.

Galactic-noise is only a dominant factor in receiving systems operating above 40 MHz. in noise-free locations. On 160 meters, as well as six meters, I can hear a substantial noise increase (I'm in a

very quiet rural location with few houses and power lines around me) when I aim my antennas at two neighboring town about 5-7 miles away.

When the bands are "open" and I am receiving distant signals the propagated noise even on the most quiet days "swaps out" the noise from the population centers around me (both towns of 7000 people).

There is a 10-15 dB noise increase at night on 160 meters, because of propagated noise, even on the most quiet winter days. On twenty meters, as well as 160, I can tell what direction the band is open by listening for a noise increase.

Now I'm sure if my antennas were above the ionosphere, galactic noise would be important. But I simply can't manage that height and even if I did I wouldn't be able to work many people below ten MHz because of the attenuation of the ionosphere.

>The graph in the "RSGB Communications Handbook" Fig 15.6 is pretty well spot
>on. However it would be useful to see the vertical scale also calibrated in
>temperature.

It may be "spot on", but it is also useless unless you know how it applies to the real world we live in. Almost anyone can learn to read, write, copy data, add, and subtract..... the real problem is understanding how to use data correctly. That's what takes time and effort.

Tom:

A general rule is 7 times the wavelength, 70 pf for 10 meters, 140 for 20 meters, etc...of course you want to be able to vary it over enough of a range to compensate for other variables at the feed.

The voltage at a gamma match feed is pretty low, even when running high power, so you don't need an expensive high voltage cap.

However, as all antennas are extremely short - by enforcement - I
would allow that each and every near/far field is identical in
geometry if not amplitude. Thus this first consideration of variation
does not seem to account for much.

By moving out to 1000 feet, the variation of 1 foot is lost in the
noise.

4918. RE: FRACTAL ANTENNAS At IEEE APS in July

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-14 17:27:13 UTC
From: Steve Sawicki <ab2et@MailAndNews.com>
Message-ID: <3ABFC9F1@MailAndNews.com>
Source record: 168488

Well I guess I know where and what I will be doing on Friday, July 13, 2001, just imagine the frenetic activity that will lead on to this gala event?

But lets lok at the practical side of thing :
After examining all of the offerings at
http://www.ewh.ieee.org/soc/aps/2001/workshop/WorkshopShort.htm

SC-3: Practical Consideration in the Design of Antennas for Wireless Communication Course fee: $200 a Full Day courses sure looks like the better deal unlike the 1/2 Day Courses SC-7: Fractal Antennas Course fee: $120

SC-3:
Course Outline: This short course will address specific topics related to the
design and fabrication of antennas for wireless communication. In the first part, we will discuss the types of antennas used in this industry, as well as
strategies for choosing the right antenna for a system. A short historical background will follow the evolution of the antenna industry from the military
technology to the emerging commercial applications of the late 90s.
The second part will focus on antennas used in the wireless communication industry: microstrip antennas and arrays, wire antennas and MMwave antennas.

In the third part of the course we will design different types of antennas using an electromagnetic simulator (IE3D by Zeland Software) and compare the results with those obtained using different software packages: NECWINPro by Paragon Technology, The Antenna Optimizer and The Yagi Optimizer by Brian Beezley, and The Antenna Radiation Pattern Software by Far Field Corp. We will
conclude with an interactive design session.

I am faced with a true Dilemma, SC-3 or go for the "gusto" I think that unlike
the Florida situation I know which is the correct Chad to punch.

73's

Donaly wrote:
"An infinite, or even an almost infinite transmission line is an abstraction."

Yes, but Reg could tell you about some undersea cables that are very long indeed.

I did not mean to stir a dispute over the validity of the "lossless line" as a simplification and as a convenience. The lossless line idea works well enough in many situations. RG-8 has a loss of about 0.1 db/100 ft at 1 MHz. For engineering purposes, the loss at shorter lengths and lower frequencies is insignificant.

I was using 50-ohm coax as an example of dissipationless resistance. If we had 100 feet of RG-8 carrying 100 watts at 1 MHz to a matched load, the 0.1 db loss in the coax would be hard to measure. Most instruments don`t have 0.1 db resolution.

In the example used in my previous posting, I used an almost endless line just as a short-hand for no reflected energy to vary the line impedance. I was giving an example of an almost dissipationless resistance, that of the coax surge resistance.

The main idea is that resistance is the name given to an in-phase voltage-to-current ratio. This ratio indicates an impedance to current which is a resistance, but it does not necessarily eat any energy. You who were taught that there is no such animal were simply misinformed.

There might be a historical factor that's being overlooked in this
discussion: A very important application of the small loop antenna
in Terman's era was LF/MF radio direction finding, particularly in
aircraft. One of the problems with this, as I remember, was the
discrepancies between null directions and true bearings as the loop was
rotated. This was traced to variations in stray E-field pickup due
to wing, tail and fuselage surfaces. Loop shielding would help
minimize that pickup, as would carefully designed, fully differential
receiver input circuitry. Some noise reduction might occur, but
the primary aim was a geometrically accurate, magnetic-only response.

Richard:

What do those charges moving along your infinite transmission line [constituting your 1 Ampere current] do when they "reach the end of the Universe"?

I believe that Douglas Adams may be waiting there at his special table in the "Restaurant at the end of the Universe" ready to count the charges as they pass by, just to make sure they still have the same number of Joules per Couloumb!

I wonder if the IEEE Dictionary editor/cum lexicographer has a table there as well? Probably next to Sadi Carnot's table! Heh, heh.

Dissipationless Resistance indeed! The answer is 42 [Joules per Couloumb?] no more no less.

Best,

-Peter K1PO

Loop shielding does not minimize that effect, except as it might be
used to improve balance or unbalance.

The shield is a tool for improving balance, but there are many ways to
skin that cat. If the shield is installed incorrectly, such as by
being non-symmetrical in grounding, it can actually hurt balance.

The "shield" is the **actual** antenna that receives the signal,
nothing more and nothing less. It behaves like any other antenna of
similar physical size, there is no magic. We simply can NOT filter
time-varing electric fields from magnetic fields, and so we can NOT
decouple the loop from the rest of the aircraft at the operating
frequency of the loop by adding a shield.

I tried the "soil the salt trick" when I had my Butternut vertical 6" above the gound. I saturated the ground in a three foot circle. That did help a little. Putting it on the roof top of my house with a 6' mast and lots of radials was the answer to my problems. The reason it helped in my case, I believe, is that the antenna is now above the main power lines for the city park and my neighborhood. I have four main feed lines running North and South over my back yard along the East edge of the city park. I knew when I bought the house that would be a problem. But I am baseball nut and I have a Little League ball diamond right next to my property line and love to sit out there and watch the kids play ball. So in my case height was the answer to overcome the power line problem.

Hello everyone.
Kb9YXM here.
I would like to start to build my own antennas for VHF/UHF. To start, I would like to build what might be a strange 6 meter antenna design.
I am trying to build a 6 meter 2 element phased array.
I was hoping someone could send me some idiot proof instructions or direct me to a website that they know fdirst hand might have information on this type of antenna.
The other quesiton is a simple one. When building an antenna, why must one use a gamma match, isnmt it possible just to use a ballun as with a di-pole?

Thanks and73's in advance.

Source record: 168506

I wrote:
"Complete loss of an in-phase reflection of signal from lossy soil will reduce the sky-wave by 3 db."

Bart, WB6HQK showed me the mistake I made. The maximum gain from an earth reflection is 6db.

Just to check before making another mistake, I checked the ARRL Antenna Book, and Ed Laport`s "Radio Antenna Engineering".

The 19th edition of the ARRL antenna book agrees with Bart. On page 3-11:
"Thus the resultant field strength at a distant point may be either 6 dB greater than the free-space pattern (twice the field strength), or zero, in the limiting cases."

Ed Laport in "Radio Antenna Engineering" says on page 515:
"The simplest case to study is that of a single elevated wire parallel to ground. The total potential on the wire is the sum of these direct and induced potentials." (directed and reflected) Reciprocity rules so it makes no difference that Ed is analyzing a receving antenna.

Since in the ideal case the direct and reflected signals can be equal in amplitude and phase, Ed`s improvement due to the reflection from ground is 6db.

Best regards, Richard Harrison, KB5WZI

An Amidon R61-050-750 ferrite rod. The Al value is 49 mh/1000t.
About 400 microhenries is what you need to resonate with a
365pf variable cap. That's what I use for my AM/FM receiver which
doesn't have a built-in AM antenna. I didn't count the turns. I
just resonated it to .5 MHz with a 365pf cap fully meshed.

Dick: You didn't say why you salted the soil, e.g., improve SWR, decrease radiation resistance, see if it made any difference as far as reported signal strength, etc.

For whatever reason, I'd be interested in what you were attempting to improve and how that improvement was measured.

I'm querying Tom because I'm interested in whether modeling or history would indicate that raising my vertical, given the extremely moist soil/water conditions I have, does any good. Don't know what "good" means so I'll await some comments from Tom.

Regards, Jim R.

It is mechanically easier to make the driven element one piece of
aluminum so there is no center insulator. That's when one needs
a gamma match. If you want to go to the trouble of insulating
the two elements of the dipole driven elements from each other,
then the gamma match is not needed.

KB9WFK,
What you say is true, but since any signal he put into
the cable would be orders of magnitude stronger than the
signals on the cable, it's almost a 'lead-pipe' cinch that
his signals are going to cause RFI. Depending on how much
signal is 'induced' in the CATV system, he may also be
responcible for fixing other people's TVs if they're affected,
not to mention the cable company's equipment. Sort of like
petting an alligator, just hope it doesn't turn around and
bite you...

I'm not convinced that the near field of a plain whip on a small sedan is identical to a whip with a large capacity hat mounted on a pickup truck. Certainly the current distribution would be different on both the antenna and the vehicle. (And remember, the vehicle is very much a part of the radiator.) I'd think this would lead to different near fields. On what basis do you claim that the near fields of all short antennas are identical regardless of current distribution or antenna length and size?

Absolutely correct!

The other loss is that extra hop, from whence that last 3 db can be a big chunk! That's what I was addressing too!

Source record: 168512

Gary: my response (in the form, principally, of queries) below should be taken in the context of my wariness for/of folks who start inferring horror, pestilence, and out right crisis through the disingenuous use of "numbers." Understand this wariness comes primarily from the constant barrage, via the news here in the U.S., of liberal views.

You'll find my queries below between the "<..>s." By-the-bye: I consider this an exercise in communicating with someone of a different culture (from the U.K. and, at first blush, of a liberal mindset - but I could be wrong about that last part so don't go off on me for that "first blush" take. This conversation is/will be a good thing, O.K.???

"Gary Peach" <xcg34@dial.pipex.com> wrote in message news:98od8jrgn2@lure.pipex.net...
Hi Richard et al. my remarks are despite the appearance otherwise are not anti American.
There seems to be something; lacking in the training of the American Serviceman when you consider the number of friendly fire incidents; particularly as this is the second time that US troops have wiped out a number of Kiwis.

<What is that "number," Gary? And why do you use the word "number"? Are you intimating there are significants occurances of friendly fire? That's what I'm inferring; e.g., two incidents out of five events would be significant - two incidents out of 10,000 events might not be significant, from a numbers standpoint. When you come up with a number of friendly fire incidents, I suspect that another number is of interest as well - how many exercises or events were conducted. That way we can quantify all of this in a probability/statistical kind of way. Do not infer that I'm trivializing the incident, Gary. People dying is not to be treated lightly. Just want to put this thread in the correct context; how many attempts, how many failures. >

It is important not to kill your own troops, but more so not to kill your allies. <Yep!>

One can understand the pressure on the individual in a battle situation or the hot pursuit of an exercise however I suggest that there is an element missing from the training and culture of American troops considering the now quite large number of such incidents.

<Here you go with that "number" thing again. I'll be interested in your count of incidents vs the number of exercises attempted. Most importantly, what "element" is missing? You appear to have the answer when I'm not certain you've quantified the problem.>

Any one that has done time in the
military will have witnessed the gung ho of certain individuals, there is probably a place for that, but it must be disciplined and controlled.

<Guess what???? That will factor in to the probability of something like this happening.>

If your friends can't tell you that you have BO, who can? :)

It was nice to see the naming of USS WS Churchill, of course many will not know or have forgotten that VVinnie had an American Mum, (sorry, Mom), and as such probably had residential rights in the US. <The realtiveness of that would be......what?>

I am sure that we will continue to work together despite this recent unfortunate incident. <The sheer economics and political surroundings between our two countries, the EU, ANZUK, the Rooskies, the "fill in the blank with any political entity or whatever," make that statement, like, weak, doncha think?>

Hopefully it will precipitate a review at the very least of training and discipline amongst the US forces.

< I spent 21 years in the military and 13 years in Federal Civil Service - it's guaranteed there is, will be, or always is planned to have a review of the training, the process employed, the color the participant's underware - you name it, it'll be dissected and evaluated - associated with these kinds of incidents!>

Of course there will be further incidents statistically they are impossible to avoid completely,

<Hey, you're stealing my thunder here>

however in Vietnam certain of the allied troops did not wish to fight with the Americans because of their indiscipline, and going on patrol high on drugs and transistor radios blaring out in the hostile jungles. (That is from the horse's mouth, not newspaper reports or enemy propaganda.)

<Has no relevance to this discussion!!! If you want to debate going out on patrol high on drugs, let's discuss that in a separate posting - no value in the setting we're establishing, I believe; "X" number of training exercises or events, "Y" number of incidents where friendlies were killed. No transistor radios blaring, no "indiscipline" quantified yet, etc. >

I suppose the polite thing is to not comment and ignore the problem, but that would be not only cowardly but irresponsible,

< It's irresponsible if the comments are slanted incorrectly or quantified disingenuously. The polite thing to do is prepare the case before presenting the findings or results. >

it was the silence of the good people that permitted such excesses as NAZI Germany 1920 -1945, not that I am comparing this incident to such deliberate mal-practice. < If you're not comparing this to that, then why did you

mention it? A liberal bent if I've ever seen one, Gary >

The fault if any is the laid back attitude of the American military culture.
< Nope!!! You can't make that assessment yet. You don't have the facts in
front of you, I suspect. Remember, figures lie, liars figure! >

Firing from the hip seems to be the accepted practice. Clint Eastwood has a
lot to
answer for. (BTW I am an Eastwood Fan, so perhaps The Duke contributed too:)
< "Firing from the hip"? Cmon, Gary - that's a metaphorical trick employed,
often, for any scenario other than the actual firing of a weapon.>

Please ignore Reg's editing of what I actually posted, it annoys me, but in
this medium there is little that can be done about it. He does get a bit OTT
once he climbs onto his partisan soap box. You can detect the stilted
phraseology, hopefully so can many others. < Stilted also means pompous or
lofty, doesn't it? I'd be inclined to place your post in that same light,
Gary. >

The references to 1942 are due to remarks of gratitude by me made in
another news group.

4938. Icom AH-2b antenna measurements

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-14 20:42:59 UTC
From: Rudy Marcelletti <rudym@net-link.net>
Message-ID: <3aafd7d7$0$62148$bbae4d71@news.net-link.net>
Source record: 168510

Anyone using one? Icom specs say the antenna is 8.2 feet long, but what is the exact length of the spring and whip? Is the whip 8.2 feet? Is the spring length included in the overall 8.2 feet?

In using my AH-4 antenna coupler with a 6" spring and 102" or 112" whip, I do not get full output from rig on 6 meters (the rig folds back) but acceptable performance on lower bands. I am thinking a slightly shorter whip would do the trick on 6, although performance would decrease even more on the lowest bands. I am mainly interested in 17, 15, 12, 10 and 6 with this setup.

Hi Gary,

You mean there's a difference? :-)

As for friendly fire, such is the risk of service that our
conservatives so put us up to, but seem so shy of sharing. I
volunteered knowing full well the problems of 'Nam and the sham it
presented the rest of the world, and that the "silent majority" (the
artifice invented by our "hawks" to bolster their failed logic) was
willing to look the other way.

You may observe that since then our politics have descended to the
gutter with drug using, draft evading, whoremongers now running our
country. They were elected by the "silent majority" and their kids
who obviously find this new low in morality suitable to their
politics.

And yet you (or others) may challenge me as to why I volunteered, or
how I hold my faith in light of such depravity in politics. Simple, I
come from the traditional school of conservatism established by
Senator Barry Goldwater (a ham) and so prostituted by his party as
they sold their birthright to plant their faces in the public trough.
This new crowd is an emasculated bunch of wimps struggling to fill
their pockets while crying about standards. If you posed this
question of Friendly Fire to them, I hope you don't expect any
component of compassion that isn't linked to an election rally.

They will pass, and we will some day return to the higher standards I
volunteered to fight for.

But enough of politics, John Donne expressed EVERYONE's problem
succinctly in:
>Meditation XVII
>Nunc lento sonitu dicunt, moricris
>Now this bell tolling softly for another, says to me, Thou must die.
>... No man is an island, entire of himself; every man is a piece of
>the continent, a part of the main.
>... never send to know who for whom the bell tolls; it tolls for thee.

The balance issue in DF was what I was trying to raise in regards to loop shielding. That is what determines bearing accuracy and that's why the early, air-core receiving loops were shielded - because they were considerably used for DF. I probably misstated the E-field pickup effect. Avery G. Richardson says it much better in Chap.28 of _Jasik_, 1st ed.:

Shielded Loop. When a loop is used in practical circuits, it is generally near grounded surfaces as shown in Fig.28-5a and is often connected to the receiver through a center-tapped transformer T. If the distributed capacities C1 and C2 between ground and opposite sides of the loop are unequal, the voltages of the loop sides with respect to ground will cause unequal currents to flow through C1, C2 and transformer T primary, with a resulting distortion of the pattern. To avoid this condition, the loop is enclosed with a metal shield as in Fig 28-5b, thus providing equal capacities to ground. The gap prevents the shield from behaving as a short-circuited turn. The shield also reduces effects of electrostatic induction fields due to precipitation static or nearby conductors.

(Fig 28-5a shows an unshielded loop over a ground plane that slants upward to the right, and Fig 28-5b shows the usual shielded loop configuration).

> The shield is a tool for improving balance, but there are many ways to
> skin that cat. If the shield is installed incorrectly, such as by

> being non-symmetrical in grounding, it can actually hurt balance.

Indeed, and most of these old articles on shielded receiving loops showed
them feeding a carefully balanced, push-pull input circuit on the receiver's
first RF amplifier.

> The "shield" is the **actual** antenna that receives the signal,
> nothing more and nothing less. It behaves like any other antenna of
> similar physical size, there is no magic. We simply can NOT filter

> decouple the loop from the rest of the aircraft at the operating
> frequency of the loop by adding a shield.

The bit about time-varying fields is true by Maxwell's equations, of course.
However, given a loop that is very small compared to wavelength, the
time-varying E field that is intimately coupled to the time-varying
magnetic field in the vicinity of the antenna is curled around those
magnetic lines. The only way this curled E-field can produce a current
flow is through a conductor parallel to it everywhere, ie: through a
closed loop. The time-varying E-field associated with the time-varying
magnetic field by virture of both being components of an incident TEM
wave is always oriented so as to induce equal-and-opposite currents in
such a loop. By producing no net current flow, it is effectively uncoupled
from its magnetic companion at the boundary of the loop.

Hi Roy,

Well it's difficult to tell if Tom agrees or disagrees or simply is
restating what I said to fill air time.

To respond directly to your question: I would speculate that being
very small in relation to the wavelength does not allow much variation
in near field geometry. However, just what constitutes near field is
obviously debatable such that it may be differentiable as you suggest.

This I can allow, and it would add difficulties to the measure in the
field. Employing three FSM's could resolve that, one would not.

As these were suggestions of a scenario, it is incumbent upon the
testers to calibrate their range and to anticipate these issues of
variation before an event occurs. Such was Cecil's agenda (I suppose)
that I was responding to. If there is variation, the solution is
simple and already discussed.

However, as this variation (of radiators) is a side issue to the goal
of a shoot-out, it would take a good crafter of testing to separate
the two while preserving the goal. I would like to see my statement
above challenged with real data (and anticipated so that it does not

confound the shoot-out). Modeled data would serve for discussion's sake too.

Hi Richard,

You have simply substituted one artifice for another to explain the first. This is called circular reasoning and is generally reserved for political debate.

If I put energy into an infinite line, I am entirely given to faith as to where it went. My professor stated simply "it never returns" and that was enough. We had a source, we had a sink, and we met the conventional meaning of dissipation whereby energy moves from one to the other.

And yet those who pray at the alter of dissipationlessness have yet to offer a reason for their benedictions (they are already without faith). So what? is the question.

It seems this hinge of dissipationlessness is the grist of a future argument so lame it cannot turn without it.

Source record: 168320

The shape of the near field isn't of any consequence for the "shootouts", since the field strength meter is placed well beyond the near field. No number of field strength meters in the near field would tell you much about what's getting to the far field unless the antennas are identical. And they certainly aren't.

I continue to maintain that simply being electrically small doesn't guarantee a particular near field. Consider, for example, a small loop and a small dipole. These have identical far field patterns, but the near fields are quite different. Then consider the intermediate antennas you could make by breaking the loop and putting plates at the gap to provide capacitance, then gradually opening it to a dipole. The near field would change a lot as you did this. And the variations of antennas being measured in the shootouts resemble these intermediate antennas in a number of ways.

It's not necessary, of course, to have a shield to have a balanced loop. And a balanced loop is, as you note, is inherently insensitive to an incident electric field. Shielding a loop may be a disadvantage, too, as the fixed capacitance of a shield reduces the frequency range over which it may be resonated.

Cortland

Thanks Roy, this resembles the information I was seeking.

Actually I have a similar problem when I read what you write Richard.

I'm unclear as to how large a problem you think the near field differences are. When I read what you write, it looks like you are saying the antennas are all very similar close to the antenna (which they are not) and it appears you conclude changes don't matter.

Then after concluding changes in antennas don't matter (or at least that is what I think you are saying), you close by suggesting measuring at three points.

I would hate for people to think the results aren't accurate because the distance is too close, or they really need to measure at three distances. That wouldn't be correct.

That's what is important, and that is where I disagree with you.

What is even more fun is when you "discover" the component lead is really a copper, or gold, plated steel wire! Use those in a circuit exposed to even a small amout of moisture, and the leads soon bust off. 8-((All you need is a small nick in the plating for that to happen. I can see why some companies spray a clear coat sealer over their boards now.

> What happened?

They seemed to work OK. I was using them in a MOSFET gate drive circuit so I did not want any extra inductance slowing the drive down.

> Ah those were the days, kids don't seem to go that route any more.
> Or is it just me?

I don't think so. If you think about it now, with the growing commercial use of surface mount parts, there is less for kids to get their hands on to play with, and learn from. The same goes when most of the guts of consumer electronics are inside of one or two uninteresting black blobs of plastic called an IC.

I was not suggesting buying that many. Some companies are willing to sell a
few "samples" at the large quantity price when they don't give away "free
samples".

> It might be with a bit oif careful engineering.

To squeeze to inductance out requires the area between the wires to trend to
zero in the "hair pin" low inductance resistor design. Of course this then
increases the capactive coupling between the wires. So you gain in one area,
and lose in another. At some point the hair pin" low inductance resistor
design just does not work that good.

Protest all you like, the information about the noise level is
incorrect. It is very well known the ionosphere shields the earth from
galactic noise below 20 MHz or so.

Anyone who has had a working system outside of a noisy local
environment also knows the conclusion was incorrect.

When the results are wrong, the data is either wrong or being
misapplied.

I'm missing something.

Can you tell me how that proves Roy's statement was incorrect?

What if I carried a closed loop of wire inside that structure?

Why does my AM radio, with a loopstick, go dead inside a metal
building? Why does a radio with a short whip work under the metal roof
of my barn, just as a loopstick does?

Roy would be a better person to address this, but as I understand it
there will be a certain soil condition where loss peaks.

When it is a perfect insulator, it looks like it is "not there". When
it is perfect, conductor it again lossless.

But I would expect in all normal cases we run into soil just isn't
that good...or rock that bad.

I'd get the antenna up in the air if I could, especially above 80
meters for a number of reasons. Ground clutter being one, earth losses
being another.

Hi Tom,

The matter is one of how to resolve anticipated problems. I care not a whit about expectations failed or otherwise.

The suggestion of three FSM's was just that. Two would do, one is leaving open the opportunity for what variation can do to upset the testing. I offered two scenarios, one close, one far. They each have their merit and they each have their cost. My style may have been over-balanced, but it was as complete as I could imagine. Choice is driven by a balance between these considerations.

Testing should be preceeded by field calibration and the observation and separation of sources of error. No amount of cogitation and hand wringing can replace real measurement and the reduction of variables.

As to how large the problem is, that falls into the category of reading tea leaves and then proclaiming the winner of a shoot-out. There is no answer without that concomitant field calibration. I offered scenarios that presented options in regard to how big the problem reveals itself in place, not in the void of the mind. If Cecil requires 1% accuracy that is easily related to geometry with little more math than stepping off the distance between the source and the sink. This one suggestion is a fundamental requirement, although not alone in the field of problems and solutions. It does not solve a problem not found, it does not solve a problem if the source of the problem is of greater scope (hence Roy's consideration). It represents a minimum standard of measurement. You can ignore it if you are satisfied that the 10% error that eclipses it is suitable for determining the shoot-off winner.

As for the angst wrought between choosing to place the FSM closer or further away - that, again, is best left to that field calibration. I offer choices, I am not making them.

Ric, I have a split personality on this subject. The left mathematical, logical, hemisphere is biassed towards measurements within the near field. The emotional right hemisphere, which yearns to hear once again the music-of-the-spheres, calls for a REAL shoot-out over a 200-mile, one-hop path, via the E-layer, on 3.75 MHz, plus or minus qrm.

Do you think that would end the arguments about how high up the antenna the coil should be ? But in how many years out of 11 could the contest be held ?

Hi Roy,

It's hard to correlate your statement that near fields aren't of any
consequence in one breath and to follow that with glaring differences
between a loop and dipole in that same near field.

My proposals simply offer if you do find variation, fix it with
distance.

I would dearly love to have a package that displays those near fields
to appreciate your concern. I share it too, but visualizing it
(through a display package rather than a near field table) is not
currently an option. I have attempted to portray them in Mathcad, but
this too has not been very satisfactory.

These differences, variation, occur in the near field as you say (and
I have no arguement), but this says nothing of what near field means
in this regard. Half a wave? 5 waves? We can all quote the math in
its generality, but I need a visual correlative of the reality
(modeled or measured).

Hey, I resemble that remark...

If a near-field strength meter is
> all that is needed for optimum performance, why bother with
> far-field measurements?
> --

Myself, I think as long as you get at least 20 ft away from the cars to be tested, it's going to be fairly accurate as far as determining the best of two vehicles. IE: the winner of the contest at 20 ft, will most likely also be the winner a 1 WL. But I also think the farther away you get, the more accurate in general. You can tell finer differences in strength. I think really you might as well just stick with 1 wl as you are doing. I sure don't think moving closer would add to the accuracy.

Depends on what you're adjusting for optimum performance. If all you're adjusting is your tuner, you can adjust it equally well by measuring the far field, measuring the near field, putting an RF ammeter in the output lead, or, like we did in the misty distant past, touching an NE-2 to the output wire and tuning for maximum brightness. No one of these methods will give you any better results than the other for determining the best tuner adjustment.

The organizers of the shootouts should take to heart the words of
Jonathan Swift, penned in 1733(*):

So, naturalists observe, a flea
Hath smaller fleas that on him prey;
And these have smaller still to bite 'em;
And so proceed ad infinitum.
Thus every poet, in his kind,
Is bit by him that comes behind.

Armchair quarterbacks have been with us since well before football was
conceived.

Richard, I've never found the concept of dissipationless resistance to be of the slightest practical value. I can't imagine that anyone else has ever done so either. I had never even heard of the stuff till I came across it in this newsgroup. From what I read here it appears only to be an endless source of light academic argument.

Just a suggestion - if anyone should object to the introduction of an infinitely long, very low loss line into an argument, don't have an infinitely long line, just have a very long line and limit attention-spans to the period before the first echo arrives back at the near end. That period can be made as long or as short as anyone could wish for.

Unfortunately, attention-spans in this modern age are a little less than the intervals between TV adverts which get shorter by the month.

I am not sure that is sufficient information to deduce that it is the gauge in the dashboard.
Some gauges have a memory that holds the last position when turned off.
If the car is off and you fill the tank, you won't see the new reading until the ignition is turned back on.

So what I need to know is whether your gauge used to drop below empty when you shut off the ignition.

Did you try to locate the sender and apply a reversed polarity voltage to it?

Hmm,

Sitting on the edge of Occam's razor. Unfortunately the crowd does
not see any virtue in having more than one FSM as a source of error.

Hi Mark,

You can do this at 20 feet, IFFF you can assure the next guy that his point of radiation is at the same, exact point as the last.

This is not a simple condition. As pointed out numerous times, the antenna is not solely responsible for what is radiated and taking it for granted that if fellow B's antenna is in the same place as fellow A's antenna, that actually says nothing about the source of radiation.

If the sources vary by 10 feet at a distance of 20 feet, you are in a world of hurt. If you push that FSM out to 2000 feet, it matters only to the degree that mulitpath might contribute error beyond the 0.5% variation.

I didn't know that, though this doesn't surprise me since there is
a lot of stuff I don't know. It does make sense that the ionosphere
would operate the same way whether the RF comes from the top or the
bottom, however, so the notion is intuitively satisfying.

Since at least part of the shielding would come from diffraction, with
the effectiveness varying with the angle of incidence, would this not
also imply that the shielding is better at the horizon than it is
vertically? And, if so, would this mean that horizontal dipoles
which have significant sensitivity in the near-vertical direction
might sometimes be noisier than vertical antennas which are relatively
deaf straight up? Particularly at night when the ionospheric absorption
of sky noise should be at a minimum?

That would defy common expectations. It would also explain how those
pre-satellite Bell Labs guys he quoted might have managed to measure such
huge sky noise temperatures (by measuring in the vertical direction?) that
you don't hear on your radio.

4972. Another AH-4 question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-15 00:47:13 UTC
From: John O'Flaherty <oflahert@toast.net>
Message-ID: <3AB01111.D6BF83BD@toast.net>
Source record: 168345

I am a new ham. I have an antenna consisting of a wire about 50 feet long, fed through a piece of RG8-X and an AH-4 remote automatic antenna tuner. I want to increase my signal strength, and I'd like to try making my wire a dipole by adding another wire extending 50 feet in the other direction. I've been told that I can just extend the other wire from the ground side of the tuner to make a dipole.
Ok, I'll try that. But it occurs to me that it may not make a true dipole, since the currents through the ungrounded wing and the grounded wing may not be balanced- especially since there is also a grounding wire extending straight down from the tuner to a ground rod.
What I'd like to try is connecting a choke balun consisting of 10 feet of RG8-X wound up in about a 10-inch diameter circle (as described in the ARRL handbook), between the AH-4 tuner and the two wings of the dipole. Now, would that force the dipole to be a dipole, and would the tuner still be able to meaningfully tune the antenna through that balun?

In other words, the antenna won't be resonant, and whatever properties it exhibits at a particular frequency will be presented to the remote tuner through the choke balun. Will it still tune? Will it arc and explode, electrocute the valuable operator, or worse, wreck the antenna tuner?

Any and all comments appreciated. Thanks.

john

4973. Re: Faraday shield antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-15 00:53:23 UTC
From: Cortland Richmond <Cortland.Richmond@usa.alcatel.com>
Message-ID: <3AB01283.1AA4590B@usa.alcatel.com>
Source record: 168346

Roy was saying that the same E-field exists inside the shield as outside. This is demonstrably incorrect. The shunting impedance of a the shield is so low that very little E-field exists inside it.

As proof, try the experiment: A magnetic field antenna such as a loop continues to operate in the vicinity of an E-field short, while an E-field antenna does not. Merely walking under a porch roof or service station canopy with a short E-field probe (such as on some wide band receivers) can drop a formerly strong signal below audibility, but a ten dollar, loopstick-equipped AM portable continues to receive. This demonstrates a shield need NOT have the same field outside and inside. If the E-field is attenuated in this manner for a largely open structure then for a much smaller one such as a loop shield, with smaller openings, it will be more so.

Too bad the analysis team didn't have a competent ham EME operator on board; he could have told you this would happen.

By the way, what frequency were you using? Your temperature seems a bit lower than is given in some of my references, although if your frequency was high enough and the moon was less than full the average temp is lower.

In the chapter, "Microwave System Calibration Using the Sun and Moon", (ARRL UHF/Microwave Experimenter's Manual) author David Shaffer gives the radio temperature of the moon as 225K.

The chapter, "EME Communications" in the same publication gives the moon temperature as about 210K , referencing, Zheleznyakov, "Radio Emission of the Sun and the Planets."

Hello Jim. Be glad to help you out if I can. That was some time ago that I tried salting the heck out of my yard in a three foot circle and mixed it with the clay. My yard is 99% clay, some fill from an old steel mill down about two feet, (found that out when I put up security fence), and now all the yard, 60' X 60' is all a paving "brick yard". But that is another yarn for another day. I was trying to increase all three points you mentioned in your post. When I bought my home ten years ago I was just a brand new General Class, and was trying out different tips I got from my fellow hams who got much better results than I did using the "salt" trick. At first I thought it was my sea level that kept me from receiving and transmitting. But the more I studied about antennas I soon realized it was not so much the soil but my lack of understanding of the "ground system". Once that issue was solved I began to experiment with radials. The main reason I put my antenna up on the roof top was not for height but for a radial system that would compliment the antenna. I am not a whiz at math so a calculator helped me with the system. I have four radials per band cut to the middle of the bands. What a difference that made in all around performance of my rigs. That was four years ago. When I tune up and call CQ I usually get a quick reply. Hope this has helped you.

Richard Clark wrote:
"So what? is the question."

It is significant, that`s what. It is meaningful that opposition can be offered to electrical flow and it does not alter the in-phase relationship between voltage and current, nor does this opposition consume power. How can it? In a transmission line, opposition is produced by a combination of purely reactive components. These are the pure series inductance and the pure shunt capacitance distributed within the wires. Pure reactances don`t consume power.

The problem is that many have been misinformed that resistance is defined as something that consumes energy while opposing current. That is the definition of a resistor. That is not the definition of a resistance. The resistor is just one of at least two types of resistance.

IEEE is correct.

Reg offered what should be sound advice:
"---just have a very long line and limit the attention-spans to the period before the first echo arrives back at the near end."

Yes, I did something akin to that while trying to explain surge impedance in an earlier posting. Alas, the initial ignition never made a sustained fire.

I also remember the countless attempts Cecil made trying to send pulses to and fro in earlier discussions trying to illuminate the gloom, but to little avail.

But, it is never hopeless. Time is required for these things to sink in and for the pieces to come together. At least, that`s how it works for me. Dr. Paul Joseph Goebbels was a devil, but there is something to be learned from clever devils. His motto was: "Repetition, Repetition, Repetition".

Best regards, Richard Harrison, KB5WZI

I'm obviously failing to communicate. I said that the near field isn't of any consequence for the shootouts. That's because the near field isn't being measured in the shootouts. The example of the dipole and loop were to illustrate that the near fields of various small antennas can be very different, and why it would therefore be a poor idea to use near field measurements for shootouts (or any other time you want to compare two antennas that aren't identical). These don't seem contradictory to me.

"Near field" can have a number of definitions, since there's no abrupt boundary. But from a half wavelength dipole, the field gets very close to having the characteristics of the far field (wave nearly planar, E/H nearly 377 ohms, attenuation proportional to distance) in well under a wavelength away from the antenna. Kraus, in Antennas, says "the boundary beween the two [regions] may be arbitrarily taken to be at a radius of R = 2L^2/lambda", where L is the maximum dimension of the antenna and lambda is the wavelength, both in the same units as R. (Note the use of "arbitrary".) This gives a boundary of a half wavelength for a half wavelength dipole. For an 11 foot whip plus a 6 foot radiating vehicle on 3.8 MHz, the boundary using this equation works out to a little over two feet, although I'd want to get a bit farther away to make sure. But there's no question that the shootout measurements are being made in the far field.

There are some software packages that'll give you really nice graphical near field plots. Most of the ones I've heard about are in the $20,000 category, but as far as I know they're readily available if you really need this capability.

Your absolutly right Doc, I did'nt even go into the RFI on both the down and upstream signals. I know that most of you understand that the CATV plant now days has both forward sigs in the vhf to uhf range and their return path is in the 3-30 mhz range. I am sure when he keyed up that it would have dire concequences for the return path portion of the plant, causing many problems with pay per view, video on demand, cable modems, and IP telephony and any assorted array of services, not to mention any harmonics that his transmitter may have..so all in all not a good thing to do... Ray K7FU

I am always willing to learn Tom perhaps you would be so kind as to instruct me in the exact nature of HF noise and wher it originates. But more importantly what is the magnitude of the noise on HF, how is it measured and a description of the Antennas used and their efficiency and pattern. This information will be useful to facilitate the calculation of anticipated thresholds and signal to noise considerations on eacdh of the Amateur bands. If ther is only good data for one band then that will be a good start to collecting and colating an accepted standard and a basis for future obervations and calculations. Ther is no garauntee that the noise will remain constant we have not been around for long enough yet to know.

> Galactic temperature is virtually meaningless over all of HF, and

Where do you get your values for sky temperature and what are they for these bands?

> thousands of random sources.

This surely must form the basis of an experiment with an HF receiver mounted
in a space craft above the ionosphere and a series of stations at the
earth's surface making simulteneous measurements of the noise. Has the
experiment been done? if yes where can I see the results?

> Galactic-noise is only a dominant factor in receiving systems

Wher is this noise generated and more iimportantly what is the magnitude of
the noise at your antenna?

> Now I'm sure if my antennas were above the ionosphere, galactic noise
> would be important. But I simply can't manage that height and even if
> I did I wouldn't be able to work many people below ten MHz because of
> the attenuation of the ionosphere.

Are you suggesting that HF noise originates in the effective terminating load formed by the high attenuation of the Ionosphere? If so what is the driving force, where does the energy come from to produce the noise?

> >The graph in the "RSGB Communications Handbook" Fig 15.6 is pretty well spot

> understanding how to use data correctly. That's what takes time and
> effort.

I think as a first step it would be a good idea to see how the data was collected and whether it has been independently corroborated. Perhaps as you have such an excellent location and an antenna farm of some magnitude you would be in a position to supply some measured data and where possible independent verification would be useful.
Perhaps you know a source of information for the sky temperatures on HF, the main consideration for the Ham community is to be able to anticipate what signals they will be able to receive on each of the bands which they are likely to be able to use. This will to a large extent determine what equipment they will require to accomplish the task. You could be instrumental (forgive the pun) in providing this vital source data.

John wrote:
"Why is noise usually vertically polarized?"

First, when we are concerned with amateur frequencies in the shortwave bands, most of the groundwave is exhausted in a short distance from its source. This is true for desired and undesired radiation alike. Attenuation increases with frequency. You may recall that hams were relegated to "200m and down" because shortwaves seemed useless for groundwaves, and that was the propagation in use at the time.

Second, The worst noise is usually produced within groundwave distance of the receiver.

Third, the horizontal antenna above ground is ineffective for groundwave production or reception. Its "mirror image" in its ground reflection is 180-degrees out of phase with the radiator. So is radiation from the two sources.
If the ground is a very good reflector, a distant receiver will receive two nearly equal and opposite signals that tend to cancel. If the ground in the path is a poor reflector, the out of phase reflected energy will be weak but so will the direct groundwave signal. Ground that is a poor reflector is also a poor propagation medium for groundwaves. So, either way, good ground or poor, the signal communications of groundwaves from a horizontal antenna is no good.

The vertical antenna launches and receives vertically polarized waves, both direct and reflected, which are in-phase. Over good soil, these travel much longer distances than horizontally polarized waves. Noise is launched and propagates just like signals. Thus, most noise is usually vertically polarized.

Best regards, Richard Harrison, KB5WZI

Source record: 168281

Roy, thanks for your time and trouble in researching all the info.

From the Belden site I obtained details of Belden 8230 300-ohm line. From the attenuation vs frequency, velocity, and dimensions it can be deduced the loss factor of the polyethylene insulant is 0.00045. This somewhat high value for Pe is due to the dense brown coloring pigment. Pigment is added to prevent damage due to prolonged exposure to UV rays.

I did the following for amusement.

A reputable manufacturer will specify cable attenuation slightly greater than the average value of production runs. Belden does not specify anything at all below 100 MHz. So to predict what might happen at HF I came up with -

Attenuation = 0.103 * Sqrt(MHz) + 0.0015 * MHz dB/100 feet which fits Belden's data between 100 and 900 MHz.

For your test frequency of 21 MHz this formula gives 0.504 dB/100 feet.

You measured it to be 0.8 dB which is considerably different. But before going into measuring accuracy there's another reason for a discrepancy - the line conductors are copper-coated steel and the manufacturer implies the line is not intended for use below 100 MHz (It is TV antenna downlead). So the copper thickness over the steel is probably no thicker than necessary for operation at 100 MHz.

If the copper was thicker than necessary at 100 MHz the manufacturer would have specified attenuation at an even lower frequency. But he didn't. And so at 21 MHz the current has begun to flow in the lossy and magnetic steel. So if you are hell-bent on winning the contest by digging those last little signal weak signals out of the noise - don't use Belden 8230 with your G5RV.

I vaguely remember we've previously discussed measurement of attenuation using a reflection coefficient meter for power level comparisons. Of all the very many electrical quantities there is only one which is more fraught with error than measurement of high RF power - and that is high RF through-power.

Better ways of measuring RF attenuation involve either impedance bridges or calibrated attenuators. And it's very useful if the two ends of the line under test can be brought close together. The problem is then reduced to determining the ratio of two voltages. If the frequency is varied until the line's input and output

voltages are anti-phase (odd number of 1/4-waves) the measurement
is reduced to a null method - a bridge - the most accurate of
all. The velocity factor is a free gift.

Then pray for rain, or go round with a watering can, and see how
things change.

Incidentally, if the Belden 300-ohm line is used in a resonant
condition, eg, as in a line transformer as described by Cecil, even
with solid copper conductors it would have a Q of only 49 at 2 MHz
and 109 at 10 MHz. Compare those two figures with the Q of coils
in an ordinary tuner. But it doesn't have solid copper conductors
!

Doesn't need to be a disc, it can be a spoked wheel configuration with nearly equal effect. You can get a roll of solid aluminum grounding wire from Radio Shack and make a circle, and how ever many spokes you want to use (4? 5?). Leave the spokes extrqa length enough to make a 1" 90 degree bend where they meet the whip. Use a small stainless steel hose clamp to clamp the spokes to the whip. Also leave a couple extra inches length so the spokes can be wound around the outer circle. Cheap, simple, effective and easily changed. The diameter of the hat stucture will depend on how much capacitance you need to add. I'd start with a 3 ft diameter one using 18 inch spokes (add about three inches for above connections) You will probably need to experiment and may need to make more than one to get your objectives met.

> The capacitance hat must be at the top of
>
> the whip in order to be most effective.

But not for effective operation, and you will have a real problem supporting it at the top of any conventional whip. Put it about a third of the way up from the coil. If you use the hat arrangement above it will be easy to experiment to find what you want to leave for the final configuration then you can rework it more permanently as desired. If you leave the whip down closer to the coil it will be self supporting if made as above.

But how can I
>
> support the capacitance hat? Is there something I can
>
> clamp to the top whip to support the hat?
>

See above.

For a mount you can get auto or truck wheel instead of a brake drum, and make up whatever added structure you need to add to it to mount the screwdriver antenna. Use sandbags or plastic milk jugs filled with water for ballast weights.

Seems to me that most noise that is propagated on power lines is
horizontally polarized simply because of the orientation of the
radiator, like with other antennae. Maybe this is why the story got
around that noise is horizontal.

> else has ever done so either. [...]

Well, there are some real world applications of the concept. Any
ordinary resistor which transforms energy into heat also does the
opposite: It produces thermal noise.

Folks who make very low noise amplifiers with matched inputs
figured that, rather than putting an actual matching resistor
at the amplifier input, it would be better to use feedback to
do the matching.

As a result, the noise produced by the observed input resistance
is lower than the noise produced by an actual resistor of the
same value. Without this trick, it would have been impossible
to make matched-input amplifiers with better than 3dB NF.

I'm not sure I understand yet. The first part of your explanation seems to say that most noise is groundwave, or short range noise, and that horizontal dipoles are relatively insensitive to groundwaves because at low elevations there is a cancellation between the antenna's pattern and the pattern of its ground reflection. That makes sense all by itself, but doesn't introduce anything yet about polarization of the noise signal, as far as my inexperienced eye can see. Then you say, essentially, that a vertical antenna has its direct and reflected signals in phase, and thus transmits and receives well at low angles. I can see that this might mean that a vertical antenna picks up more groundwaves or local noise. Is that the case? And that horizontal antennas are essentially less sensitive to local noise? But I can't see that it would say that the noise itself is vertically

polarized. Or am I missing something here?
thanks

john

4993. Re: Faraday shield antenna?

Source record: 168283

Are you saying that very little E field exists inside a coaxial cable? A coax cable can have a large E field inside, but no field or an entirely different one outside. But things change when you cut a gap in the shield. Inside a coax cable, the current on the outside of the inner conductor equals the current on the inside of the outer conductor. If you cut a gap in the shield, the current flowing on the inside of the outer conductor has nowhere to go except over the edge to the outside. So you end up with current on the outside of the shield equal to the current on the inside. Similarly, any field impinging on the coax from the outside induces a current on the outside of the shield. This has to flow around the edge to the inside, where it produces the same field inside as was impinging from the outside. That's what happens with a shielded loop.

The preceding discussion depends on the shield being at least several skin depths thick, so it doesn't hold true at audio frequencies, say.

I don't have a ready answer for your experimental results. I see several possible things at work. A filling station canopy is almost certainly well grounded, so you'd be standing under the top hat of a top loaded vertical. I'm not sure that's a good analogy for the loop shield. The loopstick equipped radio might be a lot more sensitive that the one with the short probe. So I'm not sure you can draw the conclusion you did from the experiment. I think a better experiment would be to compare shielded and unshielded loops.

Copper-clad steel conductors - resistance vs frequency :-

When frequency is low enough for the skin depth in copper to be of the same order as copper thickness, as frequency is further decreased most of the current remains in the copper. Consequently conductor resistance and line attenuation tend to remain constant with frequency.

Eventually, at very low frequencies, where the skin depth in steel approaches the same order as the radius of the steel wire, the resistance is that of the steel in parallel with the copper. At DC, with a thin copper cladding, the resistance will be slightly less than that of the steel alone.

> Best regards, Richard Harrison, KB5WZI
[snip]

Resistance does not "consume" energy. There are no relativistic effects extant in a resistor. No mass is created!

Dear Albert would roll over in his grave to hear such ramblings.

Resistors simply convert energy from one form to another, they consume nothing!

Resistors convert the kinetic energy of motion of free electric charges, generally though not always in the form of electrons, into the kinetic energy of motion, generally though not always in the form of vibrations, of atoms and molecules. Some would measure these vibrations as phonons, others as calories, others as BTU's. All measures of mechanical motion nonetheless.

That conversion of energy from electrical to mechanical motion/vibration, often referred to as "heat", is the principal intended function performed by those devices called resistors.

This function of energy conversion is universally referred to as "dissipating electrical energy as heat".

Nothing more nothing less. Now I ask, what the hexx is "Dissipationless Resistance"? Indeed!

There are lesser known devices that convert heat energy into electrical energy. Devices that convert the mechanical motion or vibration of atoms and molecules directly into the motion of electrical charges... Sort of the reciprocal of a resistor. Shall we call these "reciprocators"? What?

What shall we call these devices? If devices that convert electrical energy to heat are called "dissipation resistors" then I believe that devices that convert heat into electrical energy should be the ones to be called

"dissipationless resistors", but I prefer to create a new word for those devices.... "reciprocators" I like the "ring" of that new word. I'm going to submit that to the Chief Lecicographer at the IEEE Dictionary for the very next edition!

Richard, can you name any of these devices/effects? Their inventors? I'd like to know what the IEEE Dictionary currently calls that particular effect! It's sad to see the misguided IEEE Dictionary authors trying to rename ubiquitous, very old tried and true concepts and names. Why don't they go pick on some lesser known concepts to label or rename.

Please, Richard let's just leave those old standby's like "surge resistance", "radiation resistance", etc... alone!

Stop trying to rename perfectly understood functions, or attempt to re-label them with that "odd and ill-defined" concept called "dissipationless resistance".

That silly and unecessary conceptual contrivance, known as "dissipationless resistance" thrown out by that "crude, coarse fellow" who authored the article on resistance in that dammed abomination of lexicography called the IEEE Dictionary.

Those who truly understand what underlies have no need for such confusing artifices! Dissipationless Resistance begone!

4998. HF6V Question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-15 12:05:03 UTC
From: Robert Moughton <mailliw@peoplepc.com>
Message-ID: <tb1c03odm8s9d5@corp.supernews.com>
Source record: 168276

I recently inherited a HF6V antenna from my father and am trying to erect it. The question that I have is, How do I correctly install the Q base coil located at the bottom of the antenna? I think that the instructions are showing that I connect each end of the coil across the base insulator and across the 75ohm matching cable. Then I suppose that the radials will connect to the bottom side of this coil. Does this sound correct?

4999. Re: Vertical HF antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-15 12:16:12 UTC
From: Jim Rodenkirch <rodenkir@spawar.navy.mil>
Message-ID: <98qc4g$86o$1@newpoisson.nosc.mil>
Source record: 168280

Dick: while awaiting your reply I started thinking about what would happen when you mounted your vertical on the rood and here's what I figured would happen - you'd install radials that approached a 45 degree angle from the horizontal which is one heck of a good way to get the antenna's Zo around 50 ohms - that's a good thing. What I didn't think of was your comment regarding four radials "per band." I don't know how many bands your set up for but, assuming at least four, you've got 16 radials and that's better than a couple on the ground.

My homebrew system has about 20 + (can't remember exactly how many I installed - old age, ya know) and I'm right on top of moist soil and next to that lake so I suspect we're close to "alike" in the performance of our respective systems.

The bands of best performance for me are 40, 30 and 20. My vertical is about 23 feet high (quarter wave on 30) and I add capacitance in parallel with the feedline and ground to tune it for 20; for 40 I add a tad of inductance (hand wound coil). For 12 meters, I switch everything out and just use the 23 feet - turns out to be 5/8 wavelength. The radials vary in length from 16 feet to 30+ feet.

Great to talk to you about verticals! Love working with that antenna, improving it, changing the length and C or L values for different bands - as long as I can "roll my own" I'm happy. LOL! Regards, Jim R.

"Dick Elliott" <elliotta@netusa1.net> wrote in message news:EPUr6.380$w46.3742@newsfeed.slurp.net...
Hello Jim. Be glad to help you out if I can. That was some time ago that I tried salting the heck out of my yard in a three foot circle and mixed it with the clay. My yard is 99% clay, some fill from an old steel mill down about two feet, (found that out when I put up security fence), and now all the yard, 60' X 60' is all a paving "brick yard". But that is another yarn for another day. I was trying to increase all three points you mentioned in your post. When I bought my home ten years ago I was just a brand new General Class, and was trying out different tips I got from my fellow hams who got much better results than I did using the "salt" trick. At first I thought it was my sea level that kept me from receiving and transmitting. But the more I studied about antennas I soon realized it was not so much the soil but my lack of understanding of the "ground system". Once that issue was solved I began to experiment with radials. The main reason I put my antenna up on the roof top was not for height but for a radial system that would compliment the antenna. I am not a whiz at math so a calculator helped me with the system. I have four radials per band cut to the middle of the bands. What a difference that made in all around performance of my rigs. That was four years ago. When I tune up and call CQ I usually get a quick

reply. Hope this has helped you.
"Jim Rodenkirch" <rodenkir@spawar.navy.mil> wrote in message
news:98ogutnke1@newpoisson.nosc.mil...
Dick: You didn't say why you salted the soil, e.g., improve SWR, decrease radiation resistance, see if it made any difference as far as reported signal strength, etc.

For whatever reason, I'd be interested in what you were attempting to improve and how that improvement was measured. I'm querying Tom because I'm interested in whether modeling or history would indicate that raising my vertical, given the extremely moist soil/water conditions I have, does any good. Don't know what "good" means so I'll await some comments from Tom.

Regards, Jim R.

"Dick Elliott" <elliotta@netusa1.net> wrote in message
news:87Pr6.198.2363@newsfeed.slurp.net...
I tried the "soil the salt trick" when I had my Butternut vertical 6" above the gound. I saturated the ground in a three foot circle. That did help a little. Putting it on the roof top of my house with a 6' mast and lots of radials was the answer to my problems. The reason it helped in my case, I believe, is that the antenna is now above the main power lines for the city park and my neighborhood. I have four main feed lines running North and South over my back yard along the East edge of the city park. I knew when I bought the house that would be a problem. But I am baseball nut and I have a Little League ball diamond right next to my property line and love to sit out there and watch the kids play ball. So in my case height was the answer to overcome the power line problem.

"Jim Rodenkirch" <rodenkir@spawar.navy.mil> wrote in message
news:98nn3fhmi1@newpoisson.nosc.mil...
Actually, I worded that reply wrong, Tom as it could appear as if I was baiting you. I should have queried differently - instead of "concern with height" perhaps along the lines of "Any interest in less concern with height."

I read often of folks elevating their verticals as high as possible because of the lousy soil conditions they face. Since I'm close to and on top of moist soil and water, can I be less concerned with the height of the antenna? Regards, Jim R.

5000. Re: Anyone Remember Gotham Base Loaded Verticals?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-15 12:30:32 UTC
From: Jim Rodenkirch <rodenkir@spawar.navy.mil>
Message-ID: <98qcvg$8ca$1@newpoisson.nosc.mil>
Source record: 168467

Dave: boy, you resurrected old memories of my first ham shack back in Wisconsin, replete with one each Gotham vertical. That was 44 years ago, I was 12 years old, just passed the Novice test and had one each Novice license in hand (KN9JWV). Somehow got wind of this vertical antenna thing (for all bands, for God's sake - what a deal) from Gotham and bought it - suspect my Pop loaned me the money and I paid him back with profits from the paper route.

Anyhow, didn't know squat about antennas so we mounted that thing on a stand next to my bedroom window so I could open the window and move the alligator clip around to find the best tuning spot on that coil as I changed bands. Ran a copper wire to an 8 foot ground rod driven in to the ground in a month that did not have an "r" in the name and I was wired for stereo, or so I thought. It worked, as best as something like that could work without any radials. Found memories though of the old Globe Scout transmitter turned on some cold winter A.M., that 811 tube cooking away, the great smells emitting from that transmitter, the lights turned low and the glow of the tubes warming my innards ----- AH, the wonders and feelings of youth, or "Yoot" as Rush would express it!

Fast forward to today - I've got the same thing, so to speak out at the foot of my property. Do things a little different this time. 23 foot vertical at ground level with 20+ radials of varying length (15 - 30 feet). Can switch in capacitance for 20 meters, inductance for 40 meters, leave both out for 30 and 12, can tune the capacitance for 18 and 10. Bingo - a real vertical system this time. Total cost - around $65 dollars.

Look in the ARRL antenna book and you'll find a myriad of ways to do something vertically. Also, there's several books (one written by W6SAI - can't remember his name but I've got it at home...again, old age showing).

Regards, Jim R.

"Dave Alden (KB8VJD)" <dalden@home.com> wrote in message news:9A6D19144F696BBA.B077077167AA7F49.D055A18F5FB1E69F@lp.airnews.net... About 35 years ago when I got my Novice license at age 13, my "Elmer" gave me a Gotham base loaded vertical that had a coil at the bottom with a tuning clip. As I recall, it was about 16 ft.tall and it would tune all the HF bands.

Just for fun, I would like to build a replica of this antenna if I could find the specifications on it or plans for a similar antenna.

Does anyone have any info on these antennas?

Thanks,

Dave KB8VJD

Then don't listen to 2 meters. Is there some reason you cannot turn the dial to another band? Are you disabled? Did you forget to read the owner's manual? If 2 meters is that bad, then go elsewhere. That shouldn't be too difficult for an intellegent person like you to figure out.

You know, I simply don't understand this animosity towards the newer hams. And that is exactly what this is (animosity towards the newer hams) because I rarely see such complaints about the many troublemakers on HF. It's not like the newer hams are taking anything away from the older hams (older as hams, not age). Before the no-code techs came, the 2-meter band was completely dead. There probably weren't 25 people in the entire country using that band on a regular basis, and the number of VHF ham repeaters could likely be counted on one hand.

However, now that the no-code techs are actually using the band, and have put all those repeaters up, the older hams sit around all day complaining. Its not like the older hams have lost anything - they still have all their HF frequencies. And absolutely nobody is forcing any of these people to listen to the 2-meter frequencies. So I just don't understand what all the griping is about.

Perhaps there is some strange twisted logic at work here. Can you explain it to me, Dana? If you don't like the 2-meter band, and nobody is forcing you to listen to it, then why do you sit around listening to it (like you claimed you did above). More importantly, why do you sit around complaining about it when the situation is so easily solved (don't listen)?

I have two of the Butternut antennas. They work great with a good ground system and radials cut to the middle of each band. When you put the antenna together there should be a plastic dowel about 4" long with the unit. Do not use a wooden dowl if missing. The plastic dowl inserts into the base mount and the main body of the antenna. Attach one end of the coil to base and the other end to the main body. You can attach radials in any manner to the base post. Have fun. W9FPJ

Hi Steve:

The IEEE event should be interesting. The SC-3 course is to be presented by Dr. Tuli Herscovici, a close colleague of mine. He and I jointly developed the early version of this presentation and a similar workshop I give. Although this is sure to be a good presentation, I have to go for the gusto: SC-7.

You might also want to check out the fractal antenna session on Wednesday. Just FYI, I am going to present two papers there:

1) The Fractal Loop Antenna: A comparison of Fractal and Non-Fractal Geometries

2) A Modification of the Small Loop Approximation for Fractal and Bent Wire Loop Antennas

Take care,

Steve VE9SRB

Cool-ohms has a nice ring, but I think it is already copyrighted.

How about "non-resistor resistance"? It has a few less characters than "dissipationless resistance", but it doesn`t instantly tell you that the "non-resistor resistance" isn`t a heat producer or some other opposition to almost anything.

Best regards, Richard Harrison, KB5WZI

Reality Check Time:
(these are only my personal opinions)

1) Roy Lewallen has not infringed on Fractal Antenna Systems' or Dr. Cohen's IP. He posted an EZNEC file of a fractal loop antenna created by a third party (me). This EZNEC file is not the property of FAS or Dr. Cohen. As for copyright violation - good luck. Non FAS images of fractal loop antennas can be found in numerous places: The FAS patents (they do not provide copyright protection), the Internet, numerous IEEE publications and several undergraduate and graduate theses.

2) Phil and Chip can brag all day long about patent awards and numerous patents pending. The reality: Having a patent issued is not a verification or certification from the US Government that the claims stated in the patent are accurate, technically correct, valid, useful, novel or of any economic value. A patent examiner does not verify that the claims in the patent application are any of these things. The real bottom line is that the patent is a mechanism to protect
the patent owner in the event that the claims are all of these things and that when a third party uses them to their economic advantage or to the patent owners economic disadvantage, the patent owner can sue in court. The court
system will ultimately decide the real value of the patent. We can read and interpret all of the patent and trademark laws we want to, but its ultimately about money and how much the patent owner thinks they can win in a law suit. If someone thinks that a third party has infringed on the patent (note that a patent does not provide copyright protection) then they should sue them for any economic value lost. I am not sure what the settlement would be against someone who has gained no economic value from an

infringement or against someone who can demonstrate that they have caused no economic harm to the patent owner. Additionally, I don't think that proving patent claims to be invalid falls under the infringement criteria. That's a risk all patent owners face.

3) Infringement for "use" is just that. Use of the patent invention in a manner consistent with the intended or obvious use of the invention as outlined in the patent. Protection from third party "use" does not protect the patent holder in the event that a third party evaluates the claims and demonstrates their validity or invalidity. I don't believe that you can sue a third party for evaluating a patent, discussing their opinions of the claims, or proving the claims to be invalid or not novel.

4) In publicly stating that all hams are free to experiment and use his fractal technology, Dr. Cohen has essentially granted all hams a royalty free, non-commercial license for the use of his fractal technology and patents. So long as this use does not have direct commercial implications, he can't sue any ham for using fractal antennas. I am not certain, but he might also have a hard time suing a ham who publishes the results of his experiments.

I've wasted enough bandwidth ..

Reg, how would you answer this question: Why isn't power dissipated
by the resistive characteristic impedance of a transmission line?

Choose one or the other, either the dipole element or the ground rod,
but not both at the same time.

With a nonresonant length of wire, the impedance at the autotuner output
can be sky high, too high for a choke to do any good. Along with that
sky high impedance comes sky high voltages which can cause arcing. My
SGC-230 doesn't have a coax connector for the output for that reason.

John wrote:
"But I can`t see that it would say that the noise itself is vertically polarized."

The vertical antenna of opportunity that has its direct and reflected waves in-phase may be the radiator of your noise source. The antenna behaves the same whether transmitting or receiving. Reciprocity rules.

The noise source antenna that launches vertically polarized groundwaves is more effective, because its direct and reflected waves are in-phase, than the noise source antenna which launches horizontally polarized groundwaves.

The noise source antenna that launches horizontally polarized groundwaves is ineffective because direct and reflected waves are out-of-phase.

The better radiation launch of veritcally polarized waves from a noise source means that there is usually more vertically polarized noise out there.

Tom W8JI wrote:

>
>When the results are wrong, the data is either wrong or being
>misapplied.

Or both.

The problem with the data is that it isn't truly "sky" noise at low frequencies - it's just noise collected by the antenna. You can only truly talk of "sky" noise if you have a directional antenna so you know where the signals are coming from. At LF, antennas are not directional enough to tell the difference between noise coming from high angles or lower angles.

At VHF and above, antennas can be made sufficiently directional to tell where the noise is coming from, and there Gary's figures tie in with other known data.

At any frequency, what you actually *measure* is the noise power coming from the receiver. Using a signal generator or a noise generator to calibrate the receiver, you can then back-calculate to *infer* the noise power level at the antenna terminals. One step further is to calculate the effective noise temperature of the antenna - or rather, the antenna's RF environment.

Now that's all very fine and standard measurement. The CCIR/CCITT have published "typical" noise temperature vs frequency curves for many years, which are what RSGB adapted for their Handbook.

Where Gary's calculations go wrong, I suspect is that he missed the hidden assumption in all these measurements, namely that the antenna is close to 100% efficient. For the Beverages and small receiving loops we're talking about here, that is far from true. For a small receiving loop, for example (thin wire, no special construction like you'd use for a transmitting loop) the efficiency is about 0.1%, so BOTH the signal AND the background noise power have to be divided by 1000. I suspect the same is true of many Beverages, since the efficiency will be about the same as a vertical of the same height as the antenna (typically 6-10ft) with no special ground plane.

Then it starts to make more sense. Gary's figure of about 20,000,000K at 1.75MHz translates to about -100dBm in 500Hz, as received by a 100% efficient antenna. For a 0.1% efficient antenna, subtract 30dB, so we're somewhere around -130dBm. This is just about the same as the noise floor of a typical RX at Top Band.

OK, those were hand-waving figures, but we can see what's happening here...

ON4UN's book on LF Antennas and DXing points out that some people find they need a preamp, while others (including himself) do not. This is exactly what you'd expect when the antenna noise temperature is within a few dB of the noise floor of the RX. Whether a preamp is useful will thus depend on the individual circumstances, which could make a few dB difference in either direction. It will depend on the actual receiving antenna, the ground beneath it, the receiver, the station layout, and not least the operator's determination to dig for weak signals right down by the noise floor.

For example, ON4UN's layout brings all his Beverages fairly close to the house, so his feedline losses are very low and it's reasonable that he doesn't need a preamp. Tom's receiving antennas, on the other hand, seem to be a significant fraction of a mile away, so even on Top Band the feedline losses are not negligible; he's also in a rural location which will have a low man-made component of noise in at least some directions, so it's equally reasonable that in his circumstances he does find a preamp (or "line driver") to be a benefit.

I see what you mean now. I wonder if high voltage transmission lines would be an exception, they being horizontal, and at such a height that they might be able to radiate at a low angle?

Tom, W8JI wrote:
"We simply can NOT filter time-varying electric fields from magnetic fields, and so we can NOT decouple the loop from the rest of the aircraft at the operating frequency of the loop by adding a shield."

Terman says:
"Electrostatic shielding is obtained by enclosing the space to be shielded by a conducting surface."

Terman devotes 5 pages in "Electronic and Radio Engineering" to shielding of magnetic and electrostatic fields. While the magnetic shield will usually block an electrostatic field, the electrostatic shield usually will not effectively block magnetic coupling. Faraday shields between magnetically coupled coils are examples of this discriminatory coupling. The cans i-f coils are placed in are other examples of electrostatic shielding.

A conducting container which is small in terms of wavelength forces nearly the same potential on all its surfaces by conduction. So, there is no potentental difference to cause trouble on its inner surfaces.

Yes, that sounds correct - the inductor is connected across the feed point, with one side connected to (the bottom of the antenna+center of coax) and the other side connected to (the junction of the radials+outer sheath of coax+any "ground" connection you may have).

If you don't already have the manual, download one from:

In built-up areas, especially below 10 MHz, man-made,
locally-generated noise predominates over noise arriving via the
ionosphere.

Local noise sources radiate from domestic wiring, plumbing pipes,
phone wires, TV antenna down-leads, washing machines, shaver cords,
etc. Such noise, at its source, is obviously randomly polarised and
is radiated in random directions and elevation angles.

From one house or building in the town to another, noise
propagation can only be via very low angle and zero angle
groundwave.

Vertically polarised ground waves suffer relatively little
attenuation and will propagate for many wavelengths, perhaps miles.
MF broadcasters depend on it.

But horizontally polarised waves, characterised by horizontal
currents flowing on and just under the surface of the lossy ground,
are severely attenuated. The electric field is shorted out. So
horizontally polarised noise strength falls to an insignificant
level after 1 or 2 wavelengths.

Consequently, at any outdoors receiving point in the locality,
man-made noise is prediminantly vertically polarised, the
horizontal components, from whichever direction they arrive, have
mostly been dissipated in the soil.

The much weaker noise from the ionosphere is randomly polarised.
Get away from human habitation, such as in the middle of the
Pacific Ocean, and from a noise viewpoint, the vertical antenna
offers no advantages over the horizontal. Take a Kon Tiki trip.

The high voltage transmission line picks up and re-radiates r-f. You may have listened to a distant station on your car radio while crossing under a high voltage line and noticed a surge in signal from your loudspeaker. But this performance depends on many variables.

At a point broadside and far from the transmission line, there is rarely any significant effect because the line is usually many r-f wavelengths and every 1/2-wave the r-f in the line reverses direction. The sum of waves from the line at a distant point will therefore be just about nill.

In the direction of the line, the transmitting wave-antenna effect of the line is overshadowed by its radiating transmission line effect, in most cases.

As a bit of trivia, the rule of thumb for power transmission line energy-supply voltage is 1000 volts per mile. A 1/2-mile line should be supplied 500 volts. A 50-mile line should be supplied 50 kv.

Best regards, Richardb Harrison, KB5WZI

Jeroen, there is a resistance at the input of your low noise amplifier - it is the feedback resistance across which is a noise voltage.

I can see no connection between your example and an imaginary non-dissipative resistance. Circuit operation can be completely analysed and explained using elementary ideas such as Ohm's Law without ever having heard of an NDR. It was sorted out by Black about 75 years back.

Reg.

They are losing, or lost, the PR battle that every no code Tech has a
burning desire to get on H.F. A surprising number of Tech class operators
don't care for H.F. much. I would dare say that some of the new Hams don't
even consider access to H.F. as the "crown jewel" of Ham Radio any more.

> - they still have all their HF frequencies.

And some like to go out of their way to tweak the noses of no code Techs
about too.

With more things to do on V/UHF the lure of H.F. has declined a bit. As you
pointed out, in the past with little use of the V/UHF bands, a Tech class
had few choices for stations to work. That's now no longer true.

> Perhaps there is some strange twisted logic at work here.

Yup. The Tech class people are having fun, and some of the OTers are really
bugged about it.

>impedance matching to a 50 ohm input

Coil winding technique and placement on a ferrite rod have a great
deal of impact on the resulting inductance and Q. Unfortunately, it's
not a trivial exercise to predict how a given coil winding technique
on a given rod will behave. There are lots of equations I can cite,
but it isn't easy getting those results with any consistency.

I consider Cecil's approach to be the most pragmatic.

As for matching to a 50 Ohm input, I strongly suggest a low noise,
high impedance pre-amplifier. Remember, small loops have very high
characteristic impedances. The losses associated with just
transforming this signal to a 50 ohm input are substantial enough to
warrant a pre-amplifier of some sort.

>consume power.

Hi Richard,

This does NOT answer the question "So what?"

In phase, out of phase? Resistance is the force by which current is impeded. Heat may come of it and it is certain to come of it eventually - thus heat is so commonplace as to become transparent as a device for argument. Consume power? Imprecise meaning here fails at the level of language and science; and taints any appeal to definitions offered. This simply reveals you are drawing a box around the problem to fit the answer - not an answer to the problem.

And just what is this "problem" that is the future argument under which this wobbly dissipationlessness is suppose to support as a rubber crutch?

No, those at the altar have been fumbling with their beads rather than facing the problem of "So What?"

This is the principle crux of the situation. This argument of dissipationlessness is not in and of itself useful except as the basis of another premise which cannot thrive without it. Thus we have the prospect of suspending disbelief twice to accommodate one idea that is yet to presented.

When I worked at Intel, a group of us would camp out together. We would
meet at a preset place on a Saturday morning, decide where to camp out,
and head out at a preset time. Somebody was always late and out of range
of CB radios. I talked the entire group into getting their Tech licenses.

We then used a mountain-top repeater to keep in touch with the late
comers and direct them to the camp site. It worked out well but only
a few of the campers saw any use for HF. After all, they had given
up their CB radios and gone to the trouble to obtain Tech licenses
because HF couldn't perform the required function.

5026. Difference in Diamond Mobile Antennas?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-15 17:51:05 UTC
From: Jeff Farrar <jeff@farrar.com>
Message-ID: <di7s6.24867$H5.5602831@news1.rdc2.pa.home.com>
Source record: 168298

I am trying to decide between two different Diamond mobile antennas. The two models are:

Model Band Wavelength Gain Watts
Mount Height

SG2000HD: 2M 2-1/4 & 1-3/8 5.2 150
UHF 62
NR770HA 2M/70cm 1-1/2, 2 5/8 3.0/5.5 200
UHF 40.2

This info is straight from Diamond's site.

Right now I am only plan on using it on a 2M radio.

My pros and cons for each.

SG2000HD: Pro: gain. Con: Height, and can't use the mount I want
NR770HA: Pro: Height, I can use the mount I want Con: Gain

Questions:

1) Will I notice a difference between the two gains to make any real world difference?
2) The two antennas have a different wavelength construction. What type of terrain is each one suited best for? I live in a very hilly area.

Thanks

True. If there is no noise, there is no noise problem. But, there is a very important reason to use a vertical antenna at sea. With a horizontal antenna there is a big problem of small signals. The sea offers a very good reflection of out-of-phase signals from its surface which wipe out direct waves to and from a horizontal antenna.

Marvin Rosen wrote:
"I need info on how to make a ferrite rod antenna for the a-m broadcast band."

These can be salvaged from an old radio, but you must have reasons to build your own.

The new edition, No. 19, of the ARRL Antenna Book has information starting on page 5-6. Terman, The Radiotron Designer`s Handbook, etc. have more coil information.

If you need an impedance different from that of the tuned winding, just wind a separate coil on the core to produce whatever impedance you desire. Put the tuned circuit coil in the middle of the core for maximum inductance.

Or put another way, since you are changing antennas you need to be far
enough away that the radiation all looks like it is coming from a
single point in the distance. Looking from the antenna to the
measurement device it looks like it is a single point also.

The mobile shootouts clearly meet that criteria. One measurement
point is perfectly fine, assuming you care less about the direction
pattern. If you care about that, use one meter at one point and rotate
the car. That's easy enough to do.

The tuner, since the antenna system is not being changed, can be
measured anywhere after the tuner. Only the applied power is changed.

I should have had more sense than to get involved in this daft
discussion.

But as it's you Cecil I ought to advise you your slip is showing:-
a transmission line built from a succession of series and shunt
resistors has a resistive Zo and readily dissipates all the energy
you can shove into it. Especially if the other end is open or
short circuited.

Reg.

That statement is just not true, Reg. Some, hopefully most, of the energy you shove into it is usually dissipated in the load, not in the transmission line. And if the transmission line is open or short-circuited, it is possible to dissipate reflected power in the generator.

So I ask again, if someone asks you why a *resistive* characteristic impedance doesn't *dissipate* most of the power, what do you say? Seems to me, a 50+j0 ohm characteristic impedance is either dissipative or it's not. Seems to me, a 50+j0 ohm antenna is either dissipative or it's not.

Certainly it is both. Because Gary ignored antenna directivity as well as where the noise comes from.

>same as a vertical of the same height as the antenna (typically 6-10ft)
>with no special ground plane.

I'm speaking of 160 meters in the following:

Beverages are a bit better than that. Comparing my Beverage to my vertical which (although Gary doesn't think so) is nearly 100% efficient, and allowing for the directivity of the Beverage (which I can do two ways, by comparing my four-square transmitting array to the Beverage or the omni-vertical) my Beverages are crudely about 1% efficient.

The more directive the antenna, the less noise power it receives because noise is arriving from every direction. The primary exceptions to this are days or times when the band is "closed" in certain directions. By far the greatest amount of noise propagates in from the darkness, and it is much stronger than any ground wave source.

One factor that evens things out is at dawn or dusk, when the ionosphere allows propagation mainly in one direction. All the antennas move closer together in S/N ratio because even the omni-directional antennas are hearing noise mainly from the dark area!

This is NOT the case near a large population center, or if you have noisy power lines. In that case the extremely low daytime noise is pushed upwards. At my last QTH, even though I could not hear a "buzz", the background noise on my omni-directional antenna (which was a 1/4

wl vertical) was almost 30 dB stronger than it is at this location on
a similar antenna! That's a large difference.

>Then it starts to make more sense. Gary's figure of about 20,000,000K at
>1.75MHz translates to about -100dBm in 500Hz, as received by a 100%

>somewhere around -130dBm. This is just about the same as the noise floor
>of a typical RX at Top Band.

We can not ignore directivity and assume a non-directional antenna. My
noise floor **AT THE ANTENNA** at midnight listening towards Europe
was (using 3.5 kHz bandwidth) -123 dBm.

OM0WR the same time was is -95 dBm
DF2PY -88dBm
WA8OLN -78dBm
W4ZV -32dBm

The weakest Europeans are, of course, below the noise floor.

Using 350 Hz selectivity that noise is -133dBm.

My FT-1000D barely makes that level with 10 dB internal S/N ratio
preamp on, and that is for wider-than-SSB bandwidths! On CW, forget
it. The receiver does not have enogh gain and the IF after the narrow
filter is far too noisey.

>ON4UN's book on LF Antennas and DXing points out that some people find
>they need a preamp, while others (including himself) do not. This is

John is in a populated area, close to a chemical plant that gives him
noise.

>house,

Another source of noise.

>so his feedline losses are very low and it's reasonable that he
>doesn't need a preamp. Tom's receiving antennas, on the other hand, seem
>to be a significant fraction of a mile away, so even on Top Band the
>feedline losses are not negligible

True enough, but my measurements are at the antenna feedpoint. My
feedliune losses are generally low, because of the frequency and I
mostly use 5/8" or larger CATV-type cables.

>; he's also in a rural location which
>will have a low man-made component of noise in at least some directions,
>so it's equally reasonable that in his circumstances he does find a
>preamp (or "line driver") to be a benefit.

Indispensable, except on noisy nights or using wide modes, like SSB.

While many people debate the need for amplifiers with large antennas like Beverages, virtually evenyone finds they need them with s mall loop antennas.

You can go to the Bencher website and download the PDF file of the manual for
the HF6V. It has all of the info needed, and if you print it out, you have the
equivalent of what originally came with the antenna.

It is easy to shield a static field of one type, and pass the other field when the fields are static.

When they are time-varying, it is another issue. Take one to zero....and the other must also go to zero.

>shield usually will not effectively block magnetic coupling. Faraday
>shields between magnetically coupled coils are examples of this
>discriminatory coupling.

In the example you gave a large amount of DIRECT capacitance is isolated by a "wall" between the coils, but this a balance issue and u you are isolating the unbalanced sources! The coils are unbalanced, and the capacitance directly couples.

If you made the coils small "loops" and wound them out oif sheilded wire, you'd find the coupling remained the SAME or might even become higher!

Let me give a clear example of where adding a shield INCREASES unwanted coupling. There is a design of Beverage transformers that uses RG-174 coax in the primary, wound over a secondary winding. The shield of that coax is grounded at one end.

If you measure common mode coupling from the primary to the secondary, it is LESS with normal small wire than with the shield in place! Unbalance is also less on a floating secondary.

It's not so much you add a shield, its HOW the shield affects the system.

Now to correct that transformer design, you simply isolate the windings from each other and ground a "Faraday shield" between the windings to an independent ground . If you ground that shied to the primary, you INCREASE the common mode coupling through the transformer.

>The cans i-f coils are placed in are other
>examples of electrostatic shielding.

No, they clearly shield BOTH fields. They are "shorted turns".

>A conducting container which is small in terms of wavelength forces
>nearly the same potential on all its surfaces by conduction. So, there
>is no potentental difference to cause trouble on its inner surfaces.

The loop is in itself a small conducting container. If you put a
shield over it that allows reception of radio signals, the shield
simply becomes the antenna.

You can not shield it for time-varying electric fields, and still
expect time-varying magnetic fields to pass. Even if we could, noise
is an electromagnetic wave just like a desired signal.

We may want it to be otherwise, but it isn't. We are stuck in this
world. You can not "shield noise" without "shielding signals" unless
we are talking about things less than a few loop diameters away.

Even if we are talking about that, the real cure comes from balancing
the system, NOT from shielding.

I'm afraid that people are confusing electrostatic fields with time-varying electric fields. The former is what you get when you pet your cat on a dry day. The latter is the electric part of an electromagnetic field. I entirely agree that a shielded loop is indeed shielded from electrostatic fields. But electrostatic fields aren't a problem for me or most people, and I can't hear them with my receiver. What the loop shield doesn't shield from is time-varying electric fields.

If you touch the shield in a shielded loop, driven with 100 watts, you
will burn your fingers.

You can draw arcs, and measure voltages just as high across that gap
as if the shield was resonanted by the capacitor that is on the inner
conductor.

You can remove the capacitor that tunes the inner conductor and place
it across the gap and the loop will behave exactly the same way, as
long as the capacitor is re-resonanted. As a matter of fact, the
voltages in the system and currents all remain almost exactly the
same!!!

That's how it is, and we can't change that no matter how nice it would
be! Actually it wouldn't be nice to change that, because we would
have trouble making coupled circuits work. In this instance, link
coupled outputs would quit working. So would many antennas.

I'd take Diamond's gain figures with a large grain of salt. I've had one Diamond antenna, a RHA627 I got for my Yaesu VX-5 HT, and it was noticeably worse on all three bands than the ducky that came with the radio, despite being much longer. If you can't trust the gain figures, there's not much basis for an objective comparison.

It depends where you are at in relationship to the conductors, and
other factors.

Your dipole antenna radiates a vertically polarized signal off the
ends. Beverages are long horizontal antennas, that respond to
vertically polarized signals.

Noise is considered to be mainly vertically polarized because
attenuation along the earth "removes" any horizontal component. Get
close to the source, and it is randomly polarized.

Source record: 168392

If the RG8X is between your transceiver and the AH-4 you are fine. If you have the RG8X going from the AH-4 output to the antenna wire, I hope you have removed the outer jacket and shield. The dielectric insulation and center conductor of RG-8 type coax is OK to use in place of "genuine" high voltage cable. Your antenna starts at the output terminal. Do not hook any baluns or chokes to your coupler. If you are going for a dipole type antenna, hook equal lengths of wire to both sides of the coupler, at least 23 feet of longer. Do not use a ground wire in this configuration. You might also want to give a loop some thought. Do not use a ground wire in a loop configuration either. I like using couplers with a single wire inverted L or V over radials.

There's certainly room for confusion. I always attempted to speak
from the perspective of the units being configured with small antennas
(hence my statement that they would exhibit identical near/far field
geometries - this is not true in terms of near/far in the sense of
field as it is in the near/far sense of wavelength, my error that you
correct below) being measured by an FSM with a small antenna.

>two feet, although I'd want to get a bit farther away to make sure. But
>there's no question that the shootout measurements are being made in the
>far field.

I can live with arbitrary, thanx for the descriptive explanation.

So, being within a wavelength does not conflict with the mandate to be
in the far field if that distance is on the order of 2 feet and the
FSM is out even 10.

However, being 10 feet out brings its own problems of serious error if
you cannot assure that all candidates place their source of radiation
at the same "point." This is not something that can be taken for
granted as we all can appreciate that the "antenna" is not always the
major contributor to radiation in these shoot-offs.

Hence my solution of moving away to resolve this source of error.

In another sense, the small size of the unit's antenna (radiator) also reduces the possibility of error due to measuring variation of near fields (as near fields are extremely close to the small radiator and the FSM is always at a greater distance).

And still, one source of error remains as a simple product of geometry at a minimum (as long as we can all agree on the scales of that geometry).

Hi Steve:

Now this is FANTASTIC News, thank you for informing others and me on this newsgroup about your upcoming presentation that will be held on Wednesday July
11th.
It just makes me wonder as to the motive or motives of the originator of this
thread of excluding this important fractal antenna related information?

Again thank you this information makes it a bit easier for me to schedule my time and greatly allays my fears of the dreaded Friday the 13th and the return
night flight back to Islip from Providence (as well as save a buck or two on the flight cost).

I do hope that you can "post" the papers after the presentation for all that did not have the opportunity to attend in person.

Oh and yes it sure looks like Bean Town will be Fractelizing at least on Wednesday night for sure, see you then...

Hi Richard,

What coax and what load? Imprecision of language does not bode well for attempts to define. Again this is framing the question to match the answer. If this is your infinite line, the line is the load and it is obvious that energy has been passed from source to sink and thus dissipated by convention.

You sorely want to find heat in that infinite line, but it having no loss makes that desire one of fantasy (and thus returns us to the notion that dissipationlessness is an artifice to explain, not a reality that exhibits a property). Being just a notion does not elevate it to another argument's proof.

On the other hand, you attempt to state this as line and load separately, that too fails in that heat will be found in both as you still cannot provide a finite lossless line. Attempts to provide a low loss line may be argued, but then you are simply arguing degree, not theory. And for this separate line load combination, the power never returns and that is enough. The load may be a resistor or it may be a radiator (in fact both are radiators/dissipators of energy) and that still does not change the question "So What?"

Thanks Cecil -- I didn't notice the ".org" -- could that be a subtle attempt to deflect Spam; or does he work for the ARRL.... go figure. I'll give it another try using .net this time.

Having said that.... I just found out I already deleted the file -- not in the mood to write it again. Summary version -- good antenna, 82 DXCC's in ~5 weeks.

Richard Clark wrote:
"What coax and what load?"

Seems pedantic to me, but Richard Clark used to teach. I never did, other than some tutoring. I didn`t have the patience needed.

OK, any coax that is "low-loss" in this situation. It will be used with a matching load which was of the dummy resistance load type in my conception. I should have said so.

In the proposed case, the line would remain cool while the load warmed. The clear cause is the "dissipationless type resistance" inherent in the coax, and the "resistor type resistance" inherent in the dummy load.

Richard Clark is right. The load on the coax could have been a 100% efficient antenna. In this case the radiation resistance of the antenna would have been of the "dissipationless type" also, and there would have been no nearby heat to be measured.

The radiated energy is dissipated in one of the dictionary definitions because it was dispersed not to return. But, this is not the prevailing definition used by the electrical community which reserves the term "dissipation" to the conversion of electricity to heat.

I feel now as I sometimes do at a baggage claim watching the same old luggage go around on the carousel. I`ve seen it all before. This subject is stale indeed.

Best regards, Richard Harrison, KB5WZI

I wish to thank everyone who commented on my question about wet ladder line. My conclusions (based on group replies and private replies) are:

1. In theory, the wet line should not make much difference. (Exception: Roy's comments go against this conclusion.)

2. In practice, there can be a substantial problem -- especially on the "higher" bands (which I take to mean frequencies above 20 m).

My current use is modest -- involving a 45' dipole, up only 20', with about 110' of feed line. I plan to put up a full-wave (on 20 m) loop, with relays to open the "top" of the diamond loop, and use it for 30-10 meters. The top of the loop will be about 66' high, with about 150' of feed line, and the whole thing will be difficult to take down for changes after it is installed. I am beginning to think I should go with open line instead of ladder line. I have never worked with open line, and it looks like handling it (standoffs, feeding it through a wall, running along a basement ceiling, etc) could be a bit messy. Perhaps it is because we have had an unusually wet winter, but I am disappointed in the ladder line. Even heavy dew seems to affect it. (Several people pointed out that the high impedance of my current antenna, on most bands, contributes to the problem --- but my proposed loop has the same exposure.)

Message-ID: <3AB16C8B.32A3F977@eznec.com>
Source record: 168229

When the current on the inside of the shield encounters the hole, it has two choices of path. One is to dodge around the hole, and the other is to flow over the edge and along the outside of the shield. The fraction which takes each path is inversely proportional to the impedance the current sees. As long as a little metal is present for longitudinal flow (assuming that it isn't too long), the vast majority of current will take that path and stay on the inside. but if you cut the shield completely around the cable, and make the gap wide enough to reduce the gap capacitance across it, the current has no choice but to flow over the edge and along the outside.

I'm not sure what you mean by "cutting one end off", but if you mean completely disconnecting the shield at one end, you can bet your boots you'll ruin the shielding effectiveness (at least at frequencies above audio). Anyone with an EMC background can tell you what happens even if you connect a shield end via a pigtail. The same problem occurs that I was just talking about. The pigtail impedance can easily be as high as the path along the outside of the shield, so current is diverted there where it can radiate or, reciprocally, can cause signal ingress. Good coax fittings connect the shield all the way around the inner conductor.

You can easily set up an experiment to test these if you have some decent equipment. What you'll need are well shielded signal generator, dummy load, and receiver. Either connect the receiver to the dummy load and couple the signal generator to the outside of the connecting cable, or connect the generator to the dummy load and couple to the receiver. Then break the shield and see what happens.

I say "All is not phoo that titters".

I've just given you an example where ALL energy accepted by a line
with a resistive Zo is dissipated in the line. So your question
doesn't make sense to me.

Let's state the same thing backwards. ALL the energy which has been
dissipated in a line can only have got there via its input
terminals.

More on Belden 300-ohm ribbon.

Finally, Beldon specifies DC resistance as 2.36 ohms per 100 feet.
If the conductors were solid copper the DC resistance would be
0.888 ohms. If we knew the resistivity of the steel core used in
the cable we could deduce the thickness of the copper cladding and
so predict the attenuation at 21 MHz even more accurately. But
we'll never know. I doubt even if Beldon knows.

That's breathtakingly incorrect. The no-code Tech license came to be in 1990. The 2-meter band has been home to thousands of repeaters and a huge amount of activity since the late 1960's. I'm sure plenty of no-code Techs have participated in establishing and maintaining repeaters during the last decade, and more power to them. But the amount of activity at VHF and above prior to that was tremendous, and to say that VHF repeaters exist because of no-code Techs is just a complete distortion of history.

Does anybody know the procedure for having an individual removed from the news groups if they are as caustic as this "gentleman"? This type of abuse and attacks are totally uncalled for. It is one thing for people to have a little fun with matching barbs but this individual and others are stretching the avenues of freedom of speech beyond civilized limits. How dare he be allowed to character assassinate with the ugliness of a devil. There must be a place to report him besides the "abuse" center.

And One does not expect to produce quality anything by sending such garbage to the FCC or the ARRL. W9FPJ

Unless he threatens to harm someone, no.

I thought I was understanding, and then something slipped away. If noise is vertically polarized, why would the vertical antenna offer any advantage over the horizontal, in regards to noise? Wouldn't it be more sensitive to the noise that is polarized in its plane?

Unfortunately, I won't be able to post these papers because the copyrights
will belong to the IEEE.

Not to worry though, the final edit of my fractal antenna article for QEX
went to the editor this week. This article, titled (subject to change)
"The Fractal Loop Antenna: Understanding the Significance of Fractal
Geometry in Determining Antenna Performance" will provide a very objective
and comprehensive analysis of fractal and other bent wire loop

configurations. The focus of the article is twofold. First, the performance trade-offs associated with using fractal geometries in antennas is considered. Performance trade-offs in terms of the antenna's radiation resistance, bandwidth and efficiency are considered. Second, the significance of fractal geometry in determining the antenna performance is evaluated.

> How long did it keep up that performance?

I don't know how long it would have gone on, but I had closed IE.
Then an add popped up. I closed it.
About a minute later another popped up (web page, or at least an IE window)

Then I discovered two IE tasks running when another window popped up a
minute or two later.
Closing this one didn't work. (it would just switch back and forth between
the two)

So, I did an <ATL><CTRL><DEL> to the task manager and shut them down that
way, but even then it took several tries.

It (the page) aparently placed some code on the computer, which then called
those pages after I had left.
It went right past Zone Alarm as I had just visited the page, it thought it
was OK.

Admittedly I was a bit concerned so I was more interested in getting rid of
the thing, rather than counting how many times pages came up and how it
worked, but I think I have the sequence correct.

That has the potential of being one dangerous page.
It could be an advertizing gimick, or it could be some testing of a very

effective way to deliver things we probably don't want on our computers.
That thing could even deliver a malicious payload.

> I got the heck out of there as fast as possible, and

5092. Screwdriver Antenna as a Base & Mobile question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-16 06:22:41 UTC
From: KA6PFE <ka6pfe@pacbell.net>
Message-ID: <7wis6.13074$qv3.6179317@nnrp5-w.sbc.net>
Source record: 168410

Hello all,

The problem seems to be common, small backyard and no antenna's allowed. So I've been looking at different screwdriver antenna's that are available and of course every manufacturer's antenna is the best (just look at their web site).

There's the ATAS (I have one of those), the DK3, BB3, Stealth, and others.

Now here's the question (I hope not to create a spam war on this), which one would perform best in both a mobile and base environment using 80 thru 10 as the guideline?

As a side note, the backyard is 12ft long by 6ft wide with a 6x6 patch of dirt that I was thinking of using something like a tri-pod mount on.

Input would be appreciated.

John wrote:
"If noise is vertically polarized, why would the vertical antenna offer any advantage over the horizontal in regards to noise?"

John has it right. The horizontal antenna is better at rejecting some of the groundwave noise. The vertical antenna is more susceptible to noise because it favors vertically polarized radiation which matches the polarization of most groundwave propagated noise.

The lone vertical may have another slight disadvantage because it is completely non-directional. The horizontal dipole is almost completely non-directional too, the way they are often used. Off the ends of the dipole there are nulls in its horizontal pattern of propagation, but that pattern is for the horizontally polarized wave. The dipole doesn`t have the same rejection for vertically polarized waves off its ends. Still, if noise is predominantly from a particular direction, a position may be found which reduces the noise pick up.

Over sea water, the vertical antenna is much better than the horizontal antenna which isn`t bad, it is awful.

Destructive interference between the direct and reflected waves over sea water tends to obliterate horizontal antenna signals. The vertical antenna`s performance is better than it is over average ground. If there were much groundwave noise at sea, the vertical antenna would be much better at picking it up. Fortunately, as Reg pointed out, noise levels at sea tend to be low. So, the vertical antenna won`t be overly bothered with noise, and it will be good at sending and receiving signals. The horizontal antenna will be no good for sending signals and no good at receiving either noise or signals.

Best regards, Richard Harrison, kB5WZI

Let's not be silly .

The loop has to be resonant, and we all know at 60 Hz any loop large
enough to have any efficiency at all would have to be extremely large.

We also know that if the loop is tuned to 2 MHz, the receiver won't
respond to 60 Hz energy or to static fields. If it does, we need a new
receiver.

>ka5s@earthlink.net

That's correct, at least at any frequency where the hole was tiny in
terms of wavelength. A loop made that way would be stone dead for
receiving.

If you cut the shield entirely around the circumference, like we do in
a "shielded" loop antenna, the shield would make a dandy antenna even
if we fed the center conductor. We've probably all had that happen
when a shield connection is broken someplace along a cable.

Surely Dr. Cohen, a Doctor of Philosophy, scientist and college professor, will thoughtfully consider the facts and insights presented by his colleagues, and be grateful for the opportunity to gain knowledge from their experience and learning. What reason could anyone possibly have to anyone expect any other sort of reaction from such an esteemed scientist?

The *question* is "why is noise mostly vertically polarized".

The answer is the earth attenuates horizonatlly polarized signals
more, so all you are left with is the vertical component of distant
ground wave sources. So with random sources, which we have, all but
the vertical components are filtered out as the propagate along the
earth.

John, who says a vertical antenna has an advantage over a
horizontal in regard to noise ?

Yes it would be more sensitive.

You will only see a difference in the two different types of antennas
when you are out on the fuzzy fringe of the repeater. The higher gain
antenna*may* get thru where the other will not. However, you will
never for sure know this is true unless you have used both antennas
at the same location, same weather, same snow pack, same......

For example, I know of *particular* parking spaces in distant towns
that will allow me to transmit/receive all the way back to the home
repeater. I guess I am bouncing my signal off buildings/mts/ect just
right to make it. Move over a parking space or two and its a no
go.... Don't think a 5.2 gain over a 3.0 would have made a
difference, but then again? Amazing.

>2) The two antennas have a different wavelength construction. What type of
>terrain is each one suited best for? I live in a very hilly area.

Can not answer that. I suspect there will be cases where one will
have an advantage over the other and then again, there will be other
cases where the other will do better. A real crap shoot.

Codeman

PS

I run a Larsen 5/8 antenna with a 150 watt amp. The 5/8 wave performs well in deep dark canyons, and fits into the garage, survives thru tree branches and parking garages, bank breezeways, etc..

Have you considered using a mini loop? I built a 6' version that cover
80-15 with absolutely flat SWR on the tuned frequency. Best of all it
requires no ground system, is very effecient, although has a narrow
bandwith. I worked stations on 40m out to 500 miles when the thing was
still in my basement.

Good luck,

No, in fact, in the case I had in mind, there isn't. What I was thinking of are the charge preamplifiers commonly used in high-energy physics detectors. These things have capacitive feedback. The input impedance is nevertheless 50 Ohms *resistive*.

The equivalent input noise is much less than what would be expected from a real 50 Ohm resistor. That alone is enough to prove that this input resistance doesn't dissipate all the power that's put in.

Bob -- check all dimensions as per the manual. The distances around the fiberglass collar are critical. See Figure 1 in the manual. If you bought it used it may be assembled incorrectly.

Tune the 10M band first then 15M, 17M and finally 20M. Put the vswr meter at the base of the antenna, not back at the rig. No 12M adjustment required - they say.

You may have a blown trap as these antennas didn't like hi power, several folks here frazzled theirs. 15M set up easily on mine - very wide bandwidth, so check yours for a blown trap, an antenna analyzer should help figure out where the antenna sections resonant.

DO NOT try to horse the antenna to other bands with a tuner, several here in San Diego did this, antenna protested and blew traps. Others got away with it, but not recommended.

I had the R5 for a few years - worked fine -- liked the full bandwidth on 20M which my R-7000 won't do. A 6 meter vertical was mounted about 15 feet away - no problems.

Hi Phil:

I am not aware of the session schedule either. I am certain that you know whether Dr. Cohen will be presenting any papers at this session. I sincerely hope he does as I would enjoy meeting him and seeing his presentation(s).

I don't think Dr. Cohen will have any issues with my papers. They are purely technical in nature and give full credit to Dr. Cohen for his previous work in this area. The conclusions I arrive at are based solely on technical fact and a much more detailed analysis than Dr. Cohen presented in his CQ papers. He may not agree with some of my conclusions but that's really an issue for the broader audience. I hope he and I have the opportunity for a technical interchange of these results.

So Vince, during an emergency, are you and your family going to refuse
to be saved by an amateur radio operator who doesn't measure up to your
standards for quality? As far as emergency amateur radio operators go,
seems to me that halitosis is better than no breath at all.

Tom, W8JI wrote:
"You can not "shield noise" without "shielding signals" unless we are talking about things less than a few loop diameters away."

That is perfectly logical. There are no tags, one saying I`m signal, and another saying I`m noise, keep me out. It all looks the same to the loop.

We can place a conductive covering over a coil to provide electrostatic shielding.

Terman says:
"It is possible to shield electrostatic flux without simultaneously affecting the magnetic field by surrounding the space to be shielded with a conducting cage that is made in such a way as to provide no low-resistance path for the flow of eddy currents, while at the same time offering a metallic terminal upon which electrostatic flux lines can terminate."

Examples are Faraday shields, transformer electrostatic shields between primary and secondary coils, and shields on direction-finding loops. A shield gap is used in each example to stop those eddy currents.

Terman gives flux diagrams of solenoid coil shielding on page 37 of his 1955 edition of "Electronic and Radio Engineering". In Figure 2-19(d), one can see the symmetry of flux terminations in the short-circuited shield. We know this works. Pull the cans off the i-f transformers in your receiver and it will likely oscillate. The shields short-out the voltage differences that could be caused by unbalanced capacitive coupling. Capacitive coupling is nullified by the shield.

The fact that time-varying capacitive stress is called "electrostatic flux" is one of those oxymorons like "jumbo shrimp".How can something static be in flux? But that`s the way it is.

Best regards, Richard Harrison, KB5WZI

Just though some of you might be interested in knowing that I worked 3Gï¿½Y with a 30 foot CTSVR/UNI-HAT Vertical on a city lot on 160 meters. Cfmd 559 reports.....

Might not seem like much to some, but for those of us who live on restricted space and budgets-------it says alot for perserverance, sticktoitiveness and dedication.

It's been a long time coming getting this antenna to do what its suppose to; but with a 50' civil defense pole 28' away that caused alot of coupling I think we may have finally succeeded. Guess I better knock on wood(^(*^%^%$$#@#$@%)*&)(

On the 19th of February also worked DJï¿½MDR and EA6SX on 160 as well. Been working numerous DX stations on the other bands with only 100 watts and same antenna.

Cheers de Kï¿½CKD Dennis

I recently purchased an antenna switch and put it inline between 2 HF rigs, and 1 antenna, so I can switch between the rigs. I still receive some signals on the rig that is switched "off" . If I'm transmitting on the "on" rig, should I be concerned about the possibility of an RF signal going into the "off" rig? Probably a dumb question, and silly way of explaining it, but it works hi hi..Thanks in advance for your time in reading. 73's, Nathan KA3MTT

Cecil, W6RCA wrote:
"If there is destructive interference somewhere, doesn`t that imply constructive interference elsewhere?"

Yes, as Cecil, a leading advocate of horizontal antennas, knows better than I do, power from an antenna is like the air in a balloon. Squeeze it in one place, and it has to go somewhere else.

Fig 12 on page 3-11 of edition 19 of the ARRL Antenna Book gives vertical radiation patterns of horizontal antennas. Notable is the cancellation of horizontal radiation, which is more complete, the lower the antenna. That is, the null extends to higher elevation angles as the antenna is lowered.

I had said that "Destructive interference between the direct and reflected waves over sea water tends to obliterate horizontal antenna signals." That would be the ground wave which doesn`t have much effect on sky wave communications.

You need more height than is convenient aboard most ships to get low-angle radiation from horizontal antennas.

Even a short vertical antenna has its maximum radiation at zero elevation-angle over perfect earth. This can be seemn in Fig 16 on page 3-13 of the new ARRL Antenna Book. Sea Water isn`t "perfect earth", but it is very nearly so.

Best regards, Richard Harrison, KB5WZI

Hey Jim, Dave did not want to get advice about verticals that work.
He wanted advice on a Gotham Vertical, installed the way Gotham said
it would work.

I have done a little research on Gotham. It was run by two brothers
named Winston who, along with many other brothers, started a company
in 1931 called America's Hobby Center in New York City before World
War II. America's Hobby Center is still in business and has a web
site,
http://www.ahc1931.com/index.html

The two brothers who ultimately became "Gotham" went off into the
military, while their other brothers stayed home. When the vets came
home, apparently the other brothers would not let them back into the
business, so they started their own competing hobby company in New
York, Gotham Hobby. Gotham Hobby in the late 1940s sold such things
as model airplane supplies, their most notorious product being a model
plane engine known as the "Deezil" that barely worked. Even then,
their advertising was known for exaggeration.

The hobby business apparently was not doing too well, and Gotham Hobby
diversified into ham antennas. I know it was the same company,
because advertisements for the airplane motors had the same address as
their advertisements for antennas. They started with yagis, but
around 1955 came out with the famous "Gotham Vertical", and continued
their exaggerations in advertising, particularly with respect to this
vertical. A year or two later, they dropped "Hobby" from their name,
and became known as "Gotham". They moved to 1805 Purdy Ave. in Miami
Beach Florida. They remained in business into the 1970s, when I
assume they retired and withdrew from the business. While they sold
verticals up to the end, by their latter years they were more into
pushing Gotham quads.

Their ads in the late 1950s and early 1960s were great. One even
implied, not long after the Cuban Missile Crisis, that the fate of a

nation might depend on a message getting through, and therefore the all band Gotham Vertical was a necessity for national survival.

I was working on an article on the Gotham vertical and its creators, but just ran out of spare time to complete it.

No, a loop does not have to be resonant. Many aren't. I own several EMI receiving loops, and
work with more I don't own. None are resonant, all are shielded. It is an appropriate case.

You say, these antennas respond to an electric field, not a magnetic one. I see, when I short circuit the electric field, they keep working the same. This makes it look very much as if your explanation how shielded loop antennas work is in error.

What's wrong with this picture? Kurt sez a transmission line
with an SWR of 10:1 that delivers 100 watts to the antenna
has 67 watts of reflected power. That sounds more like an
SWR of 4.5:1 to me.

While accessing the Worldradio web page to tell Kurt of his
error, I stumbled across this:

case.

So?

>You say, these antennas respond to an electric field, not a magnetic one.

No one I know of ever said that.

I plainly said the loop MUST respond to time-varying electic fields or
it will NOT respond to time-varying magnetic fields. If you take one
to zero, the other goes to zero.

>I see, when I
>short circuit the electric field, they keep working the same. This makes it look very much
>as if your explanation how shielded loop antennas work is in error.

If you short circuit the electric field, the loop will go dead.

Here's how you short the electric field, place a jumper across the gap
in the loop's shield. That causes the shield's inside to not respond
very well to any time-varying electric fields on the outside. It also
will not respond to time-varying magnetic fields.

I see you found a source of more errors:
>Fractal antennas pose a few surprises. First, they have a tendency to be very
>broadband or multiband. Second, they can shrink the size down without coils or
>capacitors and are very efficient.
Which are about to be blown away in new material slated for
publication.

Hi Cecil,

Rather a gushing page that appears to be stylistically similar to
other postings found in this venue that are as saccharin (although I
expect that herr doktor doesn't mind that violation of copyright).
The style of both suggest a hard effort at bolstering a sagging image.

Too bad herr doktor suffered the triple whammy of a miserable patent
allowance (pittance more likely), a loss of prestige in his own
challenge and that terrible defamation of an innocent as the Wakefield
Killer. But he seems to be on the road to recovery and perhaps there
will be an amendment to that possible "legal action" so that herr
doktor is released from his possible restraining order. Here's hoping
;-)

By summer, the new disappointments :-(will not seem so looming. :-)

I think Roy hit the nail on the head. You are confusing electrostatic fields with time-varying fields.

>Examples are Faraday shields, transformer electrostatic shields between
>primary and secondary coils, and shields on direction-finding loops. A
>shield gap is used in each example to stop those eddy currents.

You are confusing common-mode shielding with differental mode operation.

...as is magnetic coupling. When you take the time-varying electric field outside the shield can towards zero, you also take the time-varying magnetic field towards zero.

>The fact that time-varying capacitive stress is called "electrostatic
>flux" is one of those oxymorons like "jumbo shrimp".How can something
>static be in flux? But that`s the way it is.

I think you are mixing definitions of flux. When we use that term in electronics, we are not saying it is changing....such as "the tide is in a state of flux".

In the context of charges, lines of flux are curves drawn to indicate the direction and density of the electric force, nothing more. It certainly does not imply the flux is in a state of flux (pardon the pun).

Brian,
All other things being approximately equal, I'd pick the antenna with the largest diameter coil. The larger diameter coils will tend to have a higher 'Q', which can't do anything but help.
With a 'patch' of ground that size to work with, I'd copper plate it and hope for the best. It sounds like your looking for a 'portable' installation (tripod mount). An arrangement of a burried pipe (at ground level(?)) with a removable post might work better. If done correctly, you wouldn't have to worry about mowing grass, just mow over the pipe.
But for the very most best'est ground, dig a hole and bury a '48 Packard in it. Be sure to make a good connection between Packard and ground on the screwdriver...(drain the gas tank)

Natahan, how much weaker are the signals on the forst rig when you
switch to the other rig?

Tune in a strong steady signal and switch the antenna off to the other
rig. How much does the signal change? How strong is the signal from
the second rig, if you run really low power? What rigs do you have?
What switch?

Without knowing that, it is impossible to answer your
question...except for wise-guy answers.

As a screwdriver builder, I'm not going to try to 'sell' you anything.
Go with what you think is best. As Doc said, try to get one with a
larger coil and heavier wire. Stay away from those that use PVC. Here,
another idea I've seen done. If you really want stealth, mount the an-
tenna horizontally in the very peak of the attic. Then run several
wires of varying length (for different bands) from the base of the unit.
For 75 meters, it shouldn't hurt to bend it and run it around the peri-
meter of the attic. Then run lengths for 40, 15, 20, 10. Due to the
"agile" nature of the screwdriver, you *might* get away with no more
than that. There are many variables with this, so your results may be
diferent--you just have to esperiment. Just a thought......

Hi Gary,

I think you would be well served if you reviewed the other thread
where Tom offered many measurements in response to you. I am at
somewhat at a loss to recommend further as I have lost that thread in
my reader. It would serve us all if Tom were to repeat them here for
continuity.

Some of those questions you pose to him in regard to his references or
corroboration are probably not going to be responded to as he provided
measurables, not modeling, formal research nor educated guesses.
Rather, you should be able to infer much of what you ask for from
these measures, once you have come to understand his system (and he
responds to those enquiries you have made in that regard). Your
effort in this regard of reverse engineering the temperatures from the
observations should be instructive.

This is an excellent opportunity for the convergence of deep
understanding with deep experience as represented by the scope of both
your activities. I hope that this thread develops an understanding
for all.

I guess that would explain the two-inch high ribbed insulator at the output of the AH-4.
I guess there's no way to used this unbalanced tuner on a balanced antenna then, because even if I disconnected the heavy wire going to the ground rod, it would still be grounded through the shield of the feed coax, and the unshielded power supply and control wires. That makes me nervous about removing the ground connection, because to the degree it is disconnected from ground to rf, to that degree rf voltages will be present on the control inputs.

The feed coax would still be grounding the ground side of the antenna tuner,
though. There are also the power supply and control wires. Wouldn't they force
the thing to be unbalanced anyhow?

I just installed a 3 to 1 switch and see the same thing. After asking some
guys in the club about it I have learned there are basically 2 kinds of
switches. One kind grounds the unused contacts which would pretty much
eliminate what we are seeing and the other lets them float. By not being
grounded there is some rf 'bleeding' over to the other contacts. Now the
consensus is not as clear as to whether or not this harmful, and if it is,
to what degree.

I've got bad news for everyone. You can ground the unused contact, and
make things much WORSE than it is with it open. It is the open circuit
that is the problem, it's the layout inside the switch. As a matter of
fact, I'd rather have a switch that floats the unused rig's ceneter
conductor than one that grounds it. The reason for that is simple. If
you ground the lead, and a shield connection opens up on he active
ports, you'll dump all kinds of power into the unused radio.

Also, if the switch has RF loops, you can drive current into the
unused port.

My rig switch opens the unused radios, and has about 80-90 dB of
attenuation to the unused port when it is terminated in 50 ohms. I can
still hear signals, but it is far from having a level that would
damage the radio. As a matter of fact, I run 1500 watts through that
switch all the time and don't bother my other radios.

The fact you hear signals does not mean you are going to damage the
radio, and certainly tuirning the radio off won't help! I've got a
friends radio here now, that he blew up because he left it connected
to an antenna while using another radio on another antenna.

Despite my advice to disconnect it, he simply turned it off. Now the
front-end is zapped.

Even if you ground it, it will have finite port to port isolation.
Layout inside the switch is the key factor, not grounding.

This is simply not true. If the screwdriver mast is braced (and it
should be braced) a two foot rigid section puts very little additional
stress on the antenna. Take a look at my mobile installation at:

You can use coax with an autotuner if you can guarantee that the
SWR will not exceed the voltage and current specs for the coax.
For instance, if you have a 10m vertical that is resonant at 28.5,
you can use an autotuner on it to cover the entire 10m band.

Bottom line is: if you want to use coax on the output of an
autotuner, you need to know the impedances that you are dealing
with in order to limit the voltage/current to values that
the coax can handle. Otherwise, forget the coax.

5148. Glass Antennas and NMO no good for 23cm?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-17 00:52:02 UTC
From: storkus@packard-hell.storkus.com
Message-ID: <98ucfilm1@nnrp.atgi.net>
Source record: 168439
Cross-posted to: rec.radio.amateur.antenna,alt.ham-radio.vhf-uhf

I drive a taxicab for a living, and have been struggling for some time now to try to figure out how to use an outside antenna without making permanent modifications. The problem, of course, is that all 4 doors of the car are opened and closed routinely while I work, making using a mag-mount with the coax going out the window a pain.
While I won't get more than 2 bands out of it, I'm considering a glass-mount antenna. Since I've never used one before, I have some questions hopefully a few of you can answer:

1. How well do they REALLY work?
2. The Larsens say they can be attached and removed easily for putting on another vehicle, while one I saw at Radio Shack said that removing it would "permanently damage" it. Realistically, how easily are they to remove and re-install as I see fit?
3. Are there any references to rolling your own? I'd love to make one for 23 cm and 6m, but I'm probably asking for too much on these bands (too much stray reactance--or maybe not enough?--on 23cm, and the whip would be physically too big at 6m to hold to the glass, most likely).

Ok, my second question is that I found and looked through the antennas in the print-version of HRO's catalog, and noticed something interesting in the Diamond antenna section: none of their 23cm antennas came in NMO mount--only with an N-connector. When I first started considering an antenna for 23cm, I really had some doubts about the NMO, not the least of which is its size relative to the small wavelength. Since I have yet to get my hands on a meter that will measure reflected power at that frequency (one of these days...), I really have no idea just how good or bad a match to my antenna I'm really getting at 23cm (as I pointed out in earlier messages, the antenna is an Austin Antennas "Pentenna", and yes, it comes in NMO). This is sort of exasperated by the fact that the bottom part of the NMO is a thru-hole that has to pass through the steel of the mag mount which in turn is connected to the shield--thus producing a short (1cm or so) run of "coax" of a very different response.
So the question is: are my fears valid? Is NMO a bad mount to use at 23cm? I've seen them used (apparently successfully) in commercial 800 MHz installations, so they seem to work there--hell, my cab is using such an arrangement! The antenna seems to work, but I have no idea how efficient it really is--it's hard to tell by reception.

Thanks again!

Mike

>R5?
>
>Jim Sullivan N7TCF
>
>
Jim,
I've had an R5 up now for over 10 years. After about 5 years I started having similar problems. I found taking the antenna apart and cleaning all connecting points(where tubes slide inside other tubes) corrected the problem. I used steel wool to do this but other abrasives would probably work. Remember, the 10 meter portion of the antenna is the section from the matchbox (black box) to the bottom of the first trap. 12 meters from the previous section to the bottom of the second trap and so on up the antenna. It appears your problem exists just above the 12 meter trap since 15, 17 & 20 are affected. If after cleaning connecting points the problem still exists, it is likely the 15 meter trap is defective since it is in the 15, 17 & 20 meter circuit. I doubt the "black box" is the culpret since it is in the entire frequecy circuitry. Cushcraft has had problems with moisture getting into the traps which can cause this. Good luck.

Message-ID: <06e5bto2hekhdtajdkp8gip6uh3o5c05bq@4ax.com>
Source record: 168442

Jim: I did read it. Dave's primary goal is to build a REPLICA of a
Gotham Vertical based on its original specifications, or plans for a
SIMILAR antenna.

Jim, to me, a replica to a Gotham Vertical means one that is a simple
multi section thin wall aluminum tube end fed through a B&W inductor
at the bottom, attached to the hot side of an unbalanced antenna coax
via an alligator clip so you can vary the inductance by changing the
tap location on the coil with the alligator clip. The ground side of
the coax attached to a ground rod. The whole thing then attached to
the side of a house or to a non conducting support via "u" straps.

I agree that the ARRL books have discussions of verticals, but I
never saw anything in there that was quite like a Gotham Vertical as I
have described it, but I may be wrong. I often am.

Anyway, its not worth getting worked up over. Everybody seems to want
to help somebody build something that works, but I think Dave wants to
build a replica of a Gotham Vertical for "historical examination",
regardless of whether it would or wouldn't work, to check for himself
exactly how accurate or exaggerated those old advertisements were.

Just wondering Jim, in retrospect, how well did that Gotham work? I
suspect your present vertical, with radials and a much more
sophisticated loading system, works much better.

Everybody have a Happy St. Patrick's Day!! ;^)

One can short circuit the electric part of the local field by shunting it with a low impedance.
It is not necessary to do anything to the loop being tested; indeed that would be counterproductive -- the objective of the test is to see what effect varying the electric field
(without varying the magnetic field) has on how well the loop receives.

The ambient electric field does go down under a grounded roof. This can be verified with a receiver, an analyzer, or a field strength meter, using antennas sensitive to the electric field. If a loop were receiving the electric field, as you say, its signal would drop in that
environment as well, but if you do the experiment, you will find it does not. (Some care has to
be taken to insure that the magnetic field is not shunted as well, but this basically means avoiding shorted turns in the structure used as an E-field shunt.)

<xcg34@dial.pipex.com> wrote:

>I am always willing to learn Tom perhaps you would be so kind as to instruct
>me in the exact nature of HF noise and wher it originates.

You could look in Reference Data for Radio Engineers, in the chapter
on Radio Noise and Interference. That chapter connects the sky
temperature data you have with real-world results...although it will
not include anything about directivity and how that effects noise
except to say "directive receiving antennas modify noise
considerably". Reference Data for Radio Engineers concludes, as I do,
galactic noise does NOT reach the earth below about 15 MHz.

Most texts on noise agree with what I have seen. Those that don't
agree can easily be proven wrong. All it takes is a few measurements
in a quiet rural location.

>importantly what is the magnitude of the noise on HF, how is it measured and
>a description of the Antennas used and their efficiency and pattern.

There are a variety of ways to measure noise level. I've already
described several times what I did. You obviously haven't bothered
reading my answers, so why should I keep repeating the same thing?

>This information will be useful to facilitate the calculation of anticipated
>thresholds and signal to noise considerations on eacdh of the Amateur bands.
>If ther is only good data for one band then that will be a good start to
>collecting and colating an accepted standard and a basis for future
>obervations and calculations.

It isn't that hard to measure.

>Ther is no garauntee that the noise will
>remain constant we have not been around for long enough yet to know.

It changes a lot with propagation and seasonal changes, as well
frequency. But of course that has already been said, several times.

>> Galactic temperature is virtually meaningless over all of HF, and
>> certainly should never be used on bands below 10 MHz unless there are
>> extreme exception to the normal application.
>
>Where do you get your values for sky temperature and what are they for these
>bands?

Who cares? Galactic noise is meaningless below 10-15 Mhz. Any galactic
noise that would somehow filter through the ionosphere is buried in

terrestrial noise.

>Can you describe your antennae and their characteristics and the effective
>sky noise temperatures that you measure?

I've offered signal levels and antenna descriptions at least three
times now. While I try to be helpful, at some point I conclude
repeating the same thing won't help. Virtually ALL of the questions
you ask have already been answered more than twice.

I can take 20 minutes and copy and repost everything, but it is a wase
of Newsgroup bandwidth. I don't think it is productive to repeat the
same thing more than three times.

If you actually read what other people wrote, you wouldn't ask the
same questions over and over. Such as this one:

>> There is a 10-15 dB noise increase at night on 160 meters, because of
>> propagated noise, even on the most quiet winter days. On twenty
>> meters, as well as 160, I can tell what direction the band is open by
>> listening for a noise increase.
>
>Wher is this noise generated and more iimportantly what is the magnitude of
>the noise at your antenna?

Asked and answered. I will repeat it one more time and I hope this
time you read it:

For a working MEASURED example, noise floor to the NE on an array of
880 foot long Beverages on a quiet winter night, using 3.5 kHz
bandwidth, is -123 dBm with no feedline loss. That's 194 nanovolts (I
have a 75 ohm system) with a very wide 3.5kHz bandwidth.

That array, after feedline losses are deducted, is typically slightly
less than 20 dB down from a 200 foot tall single element vertical with
100 200 foot long radials and a vacuum variable and large edge wound
inductor for matching, when signal levels from distant stations in the
direction where the Beverages point are compared.

>> Now I'm sure if my antennas were above the ionosphere, galactic noise
>> would be important. But I simply can't manage that height and even if
>> I did I wouldn't be able to work many people below ten MHz because of
>> the attenuation of the ionosphere.
>
>Are you suggesting that HF noise originates in the effective terminating
>load formed by the high attenuation of the Ionosphere? If so what is the
>driving force, where does the energy come from to produce the noise?

I plainly stated where the noise comes from many times, and it wasn't
ORIGINATED in the ionosphere. Let's not be silly, and out of repect
for other people's time PLEASE read what they write.

>equipment they will require to accomplish the task. You could be
>instrumental (forgive the pun) in providing this vital source data.

It's already been done Gary. Many times. My data agrees with other data that is readily available. It is nothing new or earth-shaking.

No, Leland, no one is "bugged" about that. Many of us have dedicated a
huge amount of our personal time to help make that happen, in case you
didn't know what a VE does.
What many are "bugged" about is the lowering of requirements,
especially for the highest class of license. Nothing more.

5156. 40-Meter Vertical Dipole

Newsgroup: rec.radio.amateur.antenna

In the coming weeks, I will be installing a shortened 40-meter vertical dipole (60% of full size). I have two possible mounting configurations: 1) Ground mount on a glass insulator, or 2) mounted 25-feet in the air atop my chimney.

Any educated opinions as to how the two will compare? At 7 MHz is there any ground reflection gain to be had that would add in phase with the direct wave in the far field? Thanks!

<Cortland.Richmond@usa.alcatel.com> wrote:

>One can short circuit the electric part of the local field by shunting it with a low impedance.

The impedance of a single turn "shield" around the inner conductor(s)
is the SAME as the impedance of the antenna in a loop.

That's because the outer conductor becomes the actual antenna. We
can't change that, because one the shield is several skin depths thick

If you short the electric field, you are shorting the desired signal
as well. They are inseparable.

>The ambient electric field does go down under a grounded roof. This can be verified with a
>receiver, an analyzer, or a field strength meter, using antennas sensitive to the electric
>field.

A broadcast FSM is calibrated to measure the electric field, and it
often has a "shielded loop" antenna. Despite using a shielded loop, a
FSM can indicate the electric field because it is INSEPARABLE from
the time-varying magnetic field.

If you measure a change in the electric field below the roof, you will
measure a change in the magnetic field. They are inseparable.

>environment as well, but if you do the experiment, you will find it does not. (Some care has to
>be taken to insure that the magnetic field is not shunted as well, but this basically means
>avoiding shorted turns in the structure used as an E-field shunt.)

You can change the field impedance or modify the direction of the
field, but if you take the electric field to zero the magnetic field
must go to zero. In essence, the structure becomes the antenna.

I have an R3. It's pretty easy to distinguish it from the R5. The R3
has only two traps and no radials/couterpoises. At the base is a big
motor driven tuning capacitor. That cap will actually tune the antenna
on 17 and 12 meters even though the antenna doesn't have traps for
those bands. Surprisingly it also works pretty well on those bands.

I'm in the same boat as KB9WFK. It's a 3 position switch that is not grounded anywhere. It's an antenna switch made by ParaDynamics. It seemed too good to be true for the price of it. I should know better hi hi...I'm running a Yaesu FT-920 as my primary HF rig, switching between a Kenwood TS-430S as my digital mode HF rig. The weird thing is when I tune in a very strong station on the 920, then switch over to the 430, it attenuates the signal some; but, you still can hear the signal with no problem, and the s-meter goes to zero. I'm assuming I would be better off returning it for one of the heavy duty MFJ switches ? Thanks for all the replies. 73's, Nathan KA3MTT

John,

You can tune a dipole with your AH-4 tuner by connecting the AH-4 to the dipole antenna with 450 ohm ladder line. I have been using this set up with an inverted V dipole at my QTH for the last year and it works fine. Run one side of the ladder line to the ceramic terminal on the coupler and the other wire to the ground terminal. Then hook each wire at the other end of the ladder line to each side of your dipole. Twist the ladder line every foot or so and keep it at least a few inches from any metal objects. I run mine under the roof line inserted into 2 inch pieces of 2" plastic pipe which is screwed to the roof beams. The entire setup has worked well and required no maintenance.

Seems to me 27MHz lies within that range. Is 7MHz HF? Is 4MHz HF?
Is 29MHz HF?

It has everything to do with HF configurations not being able to
deliver the required performance. Along with CW, has HF also become
such a religion that nobody can admit that VHF/UHF repeaters have some
advantages over HF without repeaters?

5169. RE: My question about Gotham Verticals

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-17 05:38:02 UTC
From: "Dave Alden (KB8VJD)" <dalden@home.com>
Message-ID: <5FEA2CBFAAFB1E3A.9FD509E865345BFF.580C5391FE85312F@lp.airnews.net>
Source record: 168460

Gee Guys,

I didn't mean to get you into a heated debate about Gotham Verticals.

As I said, I had my Gotham back around 1964 when I was 13 years old and had just received my Novice ticket. I used the antenna with a Heathkit HW-16 CW transceiver that I built from a kit. I didn't know squat about antennas at that point (Not that I know too much now!) but, I do remember that I seemed to make regular CW contacts without much trouble.

I subsequently lost my ticket for failure to upgrade to General within 2 years (the rule back then) and didn't really get back into ham radio actively until about 8 years ago.

My intent was to ask if anyone had the specs on the coil and height and construction of the antenna in order to build one. I know it ain't going to be much of an antenna but I have always been interested in simple "low-profile" antennas for small lots, apartments, and mobile use and I thought that it would be fun to play around with.

Plus, national security might depend on it!!!!!

Anyway, I do appreciate the historical information. Quite interesting how some products come to be.

I know I could cobble something together that resembled the Gotham but I was hoping that someone might know what size B&W coil was used, how tall and what diameter the radiator was etc. just to get a head start on it.

Next swap that I go to I'm going to look for some old QST's and see if I can find one of their ads. It might be fun to blow it up and hang it on the wall in the shack.

Or, if I soak the ad in saltwater and hook it to my MFJ tuner, I might be able to get a match on 160 meters.

Not all HF works like Cb, Cecil, in fact little of it does.

The best application for such an antenna would be to connect it to a
dualband radio and use it for transmitting and receiving. If you mean the
"best way" to install such an antenna a bit more info is needed. Do you
mind drilling holes in your new truck? If not, you can mount it that way.
There are clamp on antennas, mag mounts,through-glass..."best" is a very
subjective term.

Wow! that is a surprise I did not know that there were any Ham EME operators with Antenna of BEAMWIDTH 0.5° or less wide. Certainly no on 2 m anyway. :)

>
> By the way, what frequency were you using?

Deep Space, (Monn distance and beyond), Spacecraft operate with an up link frequency centred around 2,113 MHz and a downlink frequency centred around 2,295 MHz This frequency is chosen because the back ground noise if falling with frequency but the water attenuation and noise are rising with frequency and around this frequency the cross over occurs so that maximum advantage mat be taken. With very deep space spacecraft the difference of 0.001 dB Signal level can shorten the mission by many years, so every little that can help is welcome. The antenna used for the measurement that I made was 85 fett in diameter having a gain of 55 dB and an efficiency optimised at 63 % by focusing on distant noise sources (Known Stars) and adjusting the hyperbola with respect to the parabolic surface of the main dish.
The Cassegrain construction means that any over spill due to attempting full illumination of the dish surface by the feed horn spill into the coolth of space at 4°K If a direct fedd is used then the over spill looks into the ground at 300°K and thus the possible System Temperature would not be realised. The system tempereature in those day was of the order 40°K using a ruby MASER in a helium refrigerator, Maser Gain bandwidth product in excess of 30 dB, mixer noise temperature 2,500°K (10 dB Noise Figure)
The frequency allocations are channelised in order to permit simulteneous operation of many spacecraft.
The noise measurements are made by selecting off a 20 MHz wide section of the 50 MHz IF. This wide noise bandwidth provides plenty of noise power to improve mesurement accuracy. Long time constant Simple RC integrators were

used to collect the noise and provide adequate drive to a diode bridge
detector. Clever backing off voltages could be added to the detector output
so that the signal applied to a strip chart could show a measuring
sensitivity of 1 dB for 10" or more, this precision is not required but it
is nice to be able to use it when looking for needles in hay stacks. where
this facility came into its own was when using the dish in tye Radio
Telescope mode and one wished to observe a Quasar droft through the beam of
the Antenna, the Quasar being distant 400,000,000 light years the wave front
is almost, but not quite straight. the plot so produced because the Earth's
rotation is constant gives a most excellent plot of the antenna pattern.

> Your temperature seems a bit lower than is given in some of my references,

OK the figure that I quoted was not corrected by our antenna efficiency of
63% as we were mainly interested in the S/N of the images. taking 150°K and
correcting it upwards for antenna efficiency gives, 238°K whcich accords
with your figure.
Although this antenna was built using best practices and not stinted for
money the efficiency was only measured at 63% and was probaly the best
available at that time. From time to time we had visiting Radio Astronmers
that had used the facilities at differnt Radio observatories around the
world. They were always amazed when I could show a Quasar drift through and
trace out on the stip chart. The main reason being that at that time
university Radio observatories could not afford MASERS which cost half a
million Dollars to build and about 10,000 dollars a week to run.
The best they could do was parametric amplifiers giving them system
temperatures of the order 150°K
We had one for stand by.
It is amazing to see that these days transistors exist with better noise
figures and their prices are in the tens of Dollars range and no maintenance
is required.
Alas that Historic Antenna was demolished a few months ago in the most
vandalistic manner possible.

> although if your frequency was high
> enough and the moon was less than full the average temp is lower.

Yes it is true that the Sun illumination of the Moon angle does affect the
observed temperature. This effect is due to the Albedo of the Moon. 0.07
or -11.5 dB when viewed head on. This means that if you could accurately aim
a parrallel beam of 0.5° beamwidth at the moon the reflection loss will be -
11.5 dB.
If the beam width of your antenna is twice that then the figure should be
decreased by the ratio of the beamwidths squared thus a 1° beam is another 6
dB down giving a reflection loss -17.5 dB a 2° beamwidth (36 db Gain on 2m
that would be a dish 40 m diameter on 70 cm 25 m dia) gives 12 dB additional
loss giving 23.5 dB reflection loss etc.
Some how I cant see such dishes being operated by Hams
a 3m dia dish at 70 cm would have a theoretical gain of 23 dB and a beam
width of 16.7° the moon reflection loss becomes -(20 log(16.7/0.5)+11.5) dB

= -42 dB

Branegan GM4IHJ speaks of 70 cm 25 dB (dish approx 4m), Gain Antenna in his book Space Radio Handbook. later in the chapter he lamentes the loss of rotators and the problems steering such "monsters". Our 85' dish took two 50 HP hydraulic motors to position it to two thousandths of a degree and track in Hour Angle HA at a rate of 15°/hour, I mention this in passing to give the readers a feel for what is involved in this enterprise, when you get it going though it is exciting stuff. The oil pressure to drive the motors wat 6,000 PSIG supplied through thick walled steam pipe. Any trip up the antenna entailed pasiing past these pressure lines, a pin hole in the line would permit an invisible high velocity jet that was sharp enough to cut your head off before you even felt it. this system took a team of six full time to keep the hydraulics and supprt structure on top line. Clambering around on one of those structures is definitely not for the timid. Imagine hanging in a rope cradle from a galavised iron girder 200 feet above a flat concrete surface instruments all lashed on and swinging about in the breeze whilst you attempt to adjust the VSWR of a waveguide run with some G cramps. Not too bad when the Sun is shining a little, not too much, but turn on the wind and rain and the whole thing becomes a bit treacherous.

> In the chapter, "Microwave System Calibration Using the Sun and Moon",
(ARRL

>
> The chapter, "EME Communications" in the same publication gives the moon
> temperature as about 210K , referencing, Zheleznyakov, "Radio Emission of
the
> Sun and the Planets."

If you stop to think for a moment the Moon temperature is mainly due to Sun illumination It is at the same approximate distance from the Sun as us on the Earth. Our mean temperature is about 290°K (17°C) so there isn't much surprising about what we find the Moon's temperature to be. The Sun delivers about 2 kW per square foot that is the value that the Solar panels that provided the power for the Surveyors was calculated upon. You can use about the same figure less some for atmospheric attenuation on Earth.

It is interesting to note that even the best antennas are inefficient.

Do your references give any figures for Sun Noise temperature and the
varience of them?

5174. CFA-Have you built one?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-17 10:33:15 UTC
From: Dave <rni220fgi@email.com>
Message-ID: <98veol$3n2jk$1@ID-49477.news.dfncis.de>
Source record: 168465

Today I found some notes on my old CFA test which possibly might interest some.
I used the same dimensions and frequency as the article in May 93 Wireless World, so was running it at 50 MHz.
The feeders were 300 ohm balanced, about 3 feet long going into a 4:1 balun, bringing down to 50 ohms for each path(RG58).
The 90 degree phasing was done with coax, and a 'trombone' I made from an old RF Fuse unit and a cigar tube!
The dimensions were E plates 100mm dia, 125 long and the D plates (Capacitors) were 200 mm dia. The spacing was fairly large, 50mm between each.
These were the results, for those interested.

Dipole -30 dBm
Helical/1/4 gnd plane -40 dBm
1/4 wave whip(no gnd plane) -35 dBm
CFA -47 dBm (a bit worse than I
remember, strange how your memory can compensate, to make things better!)

I did this all in a day or two, and had little information, bar the WW article on what to expect. I didn't fiddle around with the dimensions/spacing either.
I used a sig gen for the TX with two attenuators as the splitter. I didn't have a vector voltmeter and adjusted for the 90 degree shift by trial and error, but remember it had little effect! Apparently that is where the answer to the CFA lies- getiing the phase relationship dead right. But when I adjusted for maximum received signal, nothing happened!
I wonder if anyone else also experienced this?
I thought I had
had thrown these notes away (July 1993), I might have another go at this now, as I can get my hands on a vector voltmeter for a weekend....Bloody shame I have thrown away the phasing unit :-(
Or, maybe not-it could have been faulty, we shall see!!!

5175. Windom vs. Longwire

Newsgroup: rec.radio.amateur.antenna

Hi,
at the moment I'm using a mini-windom (0.5-30mhz) , original length is only 4meters so
I quadrupled it to a total of 16meters. I think it's working pretty okey, but as you know
"if you can get any better .. cheap - why not"....
I was thinking about buying an MLB and attaching perhaps 20meters of cable,
does anyone know if this will really be an improvement, from what I've heard the windom
is a good antenna...
Regards

//Greg

Reg, your last paragraph said,

The much weaker noise from the ionosphere is randomly polarised.
Get away from human habitation, such as in the middle of the
Pacific Ocean, and from a noise viewpoint, the vertical antenna
offers no advantages over the horizontal. Take a Kon Tiki trip.

That made me think you were saying that not having gotten away from
human habitation, the vertical antenna _would_ offer an advantage. Sorry
if I misunderstood.

The point is that VHF/UHF has some advantages over HF, Dick.
Mountain-top repeaters around the Valley of the Sun are one
of them. No HF frequency would do what we needed done unless
there were HF repeaters and there were not any. The only reason
most of those campers got their Tech licenses was to be able
to have reliable 2500 square mile full-time coverage. There's
no reason for those guys to want to get on HF, therefore no
reason for them to want to upgrade. A few of them who have
moved away from the Valley of the Sun have become interested
in HF.

5180. Re: Installation of DX-CC 80-10M Dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-17 17:00:47 UTC
From: Mike <KA1DRZQRM@worldnet.att.net>
Message-ID: <3LMs6.2873$wQ3.240652@bgtnsc04-news.ops.worldnet.att.net>
Source record: 168254

I have one installed as a flat top using trees at either end for support. The ends are about 45' up and I allow a bit of sag in the middle. I would remove the SEP arc-plug from the center insulator as the instrucions state over 2:1SWR can cause it to go off, A barefoot 100watt rig probably has a bit more room to play SWR wise, but I would play it safe and remove the plug and use a switch in the shack that grounds out the antenna when not in use (and remember to always switch it to ground when not in use). I didnt write down the actual bandwidths but they all were acceptable when compared to homemade mono-band diploes (as expected the bandwidth would be a little less than monoband dipoles). I have both a built in automatic antenna tuner and an outboard tuner MFJ-948; and both easily touch the antenna up when getting further away from the 1:1 points.

There was a 1:1 spot within each band and it would be quite easy to tune the antenna for a different favorite spot, but I didn't find it necessary.

I have some people complain that they are hard to tune with a tuner on the 80 meter band (because it is loaded there), but I have found no real difficulty when compared to a unloaded dipole!

And on 80 meters I have been able to hold my own up against full size dipoles and other "high performance antennas".
Good luck and 73,
Mike

Hi,
The mini-windom is a reception only HF antenna from RF Systems,
stated to recieve 0.5-30mhz or so.
I dont have the exact measurements but counting from the center magnetic balun
one end is ~125cm and the other is ~250cm, sort of a dipole style antenna.
I wanted to extend this and people on the newsgroup agreed it could be done
so I extended both ends X4, so the aprox. total length is now ~15meters and it works
really good compared to the original setup.
However I've now bought a better radio (Icom R8500) and want a really good antenna
to go with the really good radio...
A good system is never better than the antenna :)
So I was thinking about a separate MLB and some wire...
I'd like it as broadbanded as possible but best reception prefered is about 8-12mhz.
And it's for reception only ....

>Gary7SLL

Hi Gary,

I would ask about your spec of 2 KW per square foot.

I have always used a loose figuring of 1KW/M**2 at noon, on an
equinox, at the equator. I can't say that I have a ready reference to
offer, but a simple browse of the net revealed one fellow's work with
solar ovens and he specifies:
>Ambient solar flux, direct beam radiation = 494.5 W/m2
at:
http://www.engr.colostate.edu/~burns/me444/project-6-data.html

or a report of my area seeing an annual average of 145 W/M**2
http://faldo.atmos.uiuc.edu/FINGERPRINT/IMAGE2/csiro.frsa.ann.gif
Ireland, Scotland, and Britain see only 100 W/M**2

It sounds as though you are quoting for the cellular array, not a
cell.

I can quote some optical measurements related to the sun and moon in
their Luminance values from Burle's Photomultiplier Handbook:

Source candelas/M**2

Sun 1,600,000,000
Clear Blue Sky 7,900
Moon 2,500

the tube you are looking at ... 170

John wrote:
"That made me think you (Reg) was saying that not having gotten away from human habitation, the vertical_would_ offer an advantage."

The vertical antenna is much better at sending and receiving ground waves than is a horizontal antenna. That is why medium wave broadcasters all use them.

Usually, most noise is vertically polarized. That`s because vertical noise sources are more effective at launching ground waves than are horizontal sources.

Reciprocity rules, so within ground wave signal range of a noise source, the vertical antenna will pick up more noise because it is better at picking up ground waves, just as it is more effective at launching them, and it suffers no loss in effectiveness from cross-polarization. Propagation along the ground has little effect on the wave`s polarization.

In a remote location where sky waves produce the only signals and noise to be heard, the horizontal antenna loses its cross-polarization loss to signals and noise because polarization is scrambled in the reflection process by the ionosphere. Thus, the vertical is no different from the horizontal as to polarization, except the horizontal antenna over sea water is a weak performer for for both signal and noise reception. If you have enough signal and noise to hear from your receiver, the S/N ratio should not be affected by the antenna`s lousy performance. It is equal opportunity with regard to signal and noise.

The vertical antenna will have stronger reception over sea water but that includes noise as well as signal. So, the vertical antenna shows no signal to noise ratio advantage over the horizontal antenna in most cases as Reg said when you are in the middle of the Pacific Ocean.

Best regards, Richard Harrison, KB5WZI

Ash wrote:
I`d like it as broadbanded as possible but best reception preferred is about 8-12 MHz."

Back in 1937 we got a new 17-tube GE radio complete with a "V-Doublet" antenna kit.

We had an L-type aerial and a ground rod in place like most other people at the time. When we put up the dipole, we got rid of much noise and received a lot more stations. The doublet kit included transformers to maintain balance on the twisted-pair feedline.

I`d trash the Windom and go for a balanced system.

Best regards, Richard Harrison, KB5WZI

It isn't necessary to actually have an 0.5 deg BW to know that the
moon is a hot rock and radiates as such. But since you asked, I
believe an acquaintence of mine, Jim, WA7CJO, does have a 0.5 deg. BW
on the antenna he used to make the first ham EME QSO on 10 GHz.

Monsters? Four meters is a monster?

My friend John, W7BBM, has been operating a homemade 40 ft dish on
144, 432 and 1296 MHz. for over 20 years. (See the cover "CQ VHF"
magazine for Nov, 1996.) This was for EME only; it could not point at
the horizon. To overcome this limitation, he has just completed a
tower-mounted 30' dish. This is entirely homebrew welded steel
construction and he assembled and mounted on top of a homebrew tower
singlehandedly. He is receiving good echos and making QSOs on 1296
MHz using an output power of 11W.

>
I'm afraid the so-called "Space Radio handbook" is actually all about satellite communications - active satellites, that is. The author had no experience of EME, and no conception of the important differences in technologies required. The fact that a conventional rotator won't handle an EME-sized dish is only part of it.

A 4m diameter dish for 70cm is a toy. It isn't big enough (in wavelengths) to be acting as an efficient reflector, and it's impossible to feed it effectively without significant blockage by the feed antenna itself.

I can see exactly where the estimate of 25dB comes from, namely the naive use of a textbook formula that only applies for dishes that are many wavelengths in diameter - many more than 6, that is. Also the formula totally ignores feed efficiency and blockage, which are real killers for a small dish at UHF. In reality, you can expect well under 20dBi from such a dish.

The transition between a dish being "big enough" and "too small" is very sharp. On 70cm it's somewhere around 5m diameter. A 6m (20ft) will really work well, but a 4m dish is a total waste of time.

Richard Clark wrote:
"Ambient solar flux, direct beam radiation =
494.5 watts/meter squared."

My little Solarex book says their 2-in dia. solar cell has a peak output of 0.225 watts. So, that would be 5.16 watts per square foot.

Solarex says the cell is 11% efficient. So, that gives 46.9 watts per square foot into the cell or 505 watts per square meter.

Close enough to Richard Clark`s number.

Best regards, Richard Harrison, KB5WZI

A series-coil-matched 2M 5/8 wave antenna works fine.
But, *not* the capacitor-tapped-on-a-coil type.

I.e., a 2M 5/8 wave antenna that measures continuity from
the center conductor to the whip, and *does not* measure
any continuity from the whip to the shell should work.
You might need to extend the whip and inch or two for
the 50.1-50.2 range. I've used RG-58-style braid slipped
over the tip and held in place by tying a loop of lacing
cord above and below the tip ball to get the extension.

Hello Jim and thanks for your comments. Your right I have a bunch of wires up on the roof. About 28 of #14 stranded copper wire spread out like a spider web and a lone set of four #14 s.c.w., independent of any bands, connected to the mast and to a buried 6 foot copper rod. The system tunes up quite well and I very pleased with the "solid contacts". When the antenna was 6 inches off the ground I had to try and try and try to get in on a pile up. Now when I to go back to our Ham Brothers on either side of the "ponds" I get a response on the first or 2nd try. Some of my Rigs I use here at the shack are an Alinco DX70T. This is an outstanding little rig. I also use on occasion a SB104A, HW9, and HW5400 which by the way is my very first HF rig I began building way before I became a ham. I really enjoy reading about antennas and building them. My favorite quick and dirty camping antennas I use with the Alinco or HW9 is a slinky and/or a rotor cable cut for several bands. I have had a lot fun at camp grounds setting up my slinky either in a vertical or adding another slinky and making an inverted V. Over on 2ms and 70cms I have some home made 1/4 wave vertical ground plane antennas made from coat hangers and a SO239 connector. My main 2m antenna has been in service since April of 1987. It is up in my attic and works great. Any way I love antennas and have learned quite a bit more since downloading this site.

Vertical antennas DO offer an advantage on low frequency bands,
assuming the location has relatively low groundwave noise levels. You
do not have to be at sea to experience such locations.

Every array I use on 160 meters is vertically polarized (even my
Beverages), and my arrays of short phased-verticals are among the best
antennas I have. As a matter of fact, the most popular low-band
receiving antennas are almost always vertically polarized antennas.
Beverages are vertically polarized antennas, and people use them with
great success.

It's darn near impossible to build an effective antenna that is
horizontally polarized on lower bands, because it's tough to get
enough height.

Day or night, longer distance signals usually have higher S/N ratio
on my omni-directional transmitting vertical than a high dipole (I do
mean high, 300 feet).

The reason is simple, the dipole isn't all that directive....and the
vertical receives (and transmits) better at long distances. While the
vertical isn't quieter, it has stronger signals from distant stations.

So while verticals aren't quieter, they can be very effective antennas
if you are not bombed with groundwave noise.

IF you mean announcement of the Fractal Antenna reflector?

Of course not.

What right do you have to discourage those who may wish to know about it? In
the last week 30 more people joined.

Only the usual trouble makers posted (false) complaints. Now what does that say there Patricia?

Jim,

Probably the cheapest and easiest 6m mobile antenna is a Radio Shack
102" steel CB whip. Cut it down to 1/4 wave on 6 and away you go.
Depending on your individual mounting system/location the length will
be something in the 54" range. Start long and adjust length carefully
and in small increments.

Dr.Cohens participation is the "filtering" mentioned. He edits ALL
posts, and lets only those get out that he approves of. His editing
often consists of comments interjected into the posts submitted.

The "trouble makers" really include some people with impressive
credentials re antennas. THey include one who has refuted Chips
claims,and beat his performance, and another that has publihed MUCH more
on Fractal antennas than Chip.
However, there is serious doubt that the signatures on these posts from
"FRactenna" are truthful- THey are probably from Cohen, signing the name
of an underling, to avoid some kind of problem. That is just my
opinion, but there is past evidence that he has done so, frequently.

====================

Sorry John, It was my fault. I implied the opposite of what I
meant.

If noise is randomly polarised from ALL directions there's no
advantage from either antenna polarisation. As this is fairly
obvious it would have been better if I said nothing. You have the
right undersatanding otherwise you would not have asked for
clarification.

A 20 METER "CLOUDWARMER"
I thank you for showing an interest in my antenna which was voted theA number one wire antenna is North America by an independent research organization: AF2Y Enterprises! I did NOT invent it; the idea was given to me by WB2OTK in South Carolina. He didn't invent it either. Who then did? I don't know; I don't care; all I know is that it works like a BOMB! Furthermore the U.S. military is using it under the name N.V.I.S.(Near Vertical Incidence Skywave). In 30 years on the air, it is the best wire antenna I've ever used and can easily challege commercial beams for effectiveness.

A few basic concepts to begin with. A "Cloudwarmer" is a MONOBAND 2 element wire beam. I stress MONOBAND and it can be erected for ANY BAND. Secondly it is based entirely on mathematics and is uncomplicated. Thirdly, all that's required is standard wire, 52 ohm coax of any length and five insulators. Also I do not recommend using a tuner because if the construction is correct and adjustments,if necessary are made, a tuner will be unnecessary and furthermore it may mess up the mathematical relationships which govern this antenna. Lastly, any ham who can set up a standard dipole can EASILY construct a Cloudwarmer. And if any ham cannot construct a standard dipole, then he or she has no business being on the air therefore delete this information and take up basket weaving!

Keep this in mind because it applies to any Cloudwarmer for any band. The "Warmer" consists of a driven element called a dipole with a parasitic called a reflector the latter of which is 6% longer and placed between .15 and .2 wavelengths below and parallel to the driven element or as NEARLY parallel as possible. THAT'S IT. It is also known as a "SCATTERBEAM" because the RF hits the ionosphere at high angles and then scatters all over the world. It is a COMPLETELY NON-DIRECTIONAL ANTENNA on the order of a vertical but better than one for INTENSIFIED OMNIDIRECTIVITY.

Now for the mathematics. Let's talk about the numerical figures regarding wavelengths. Let's say a 20 meter HALF WAVE dipole is to be constructed to resonate with a very low SWR at 14.300. Using the formula 468/frequency , we see that such a dipole must be 32.7 feet which equates to 32'8". Let's now convert that to inches. 32' x 12 =384 inches +8=392 inches. That's a HALF WAVE. Double it and we get 784 inches therefore we now know there are 784 inches in a FULL WAVE dipole FOR 14.300. The reflector we discussed which ALWAYS GOES BENEATH the dipole i.e. driven element can be between .15 to .2 wavelengths in distance. What then has to be the length it we place it, for example .15 wavelengths below? Simply multiply 784 x .15 and we come out with 117.6 inches and divide by twelve to convert to feet and we get 9.8 which is 9 feet,10 inches. That is the minimum distance the reflector must be placed underneath the dipole. The maximum is .2

wavelengths and to change that to feet multiply 784 x .2=156.8 inches, divide by 12 and we come up with 13 feet. We now know that the reflector can be placed from 9 feet, 10 inches to 13 feet below. MIne is at 10 feet; supposedly increasing the distance will give more gain but I do just fine right where it is.

The reflector must be 6% LONGER than the dipole. We already know the length of that dipole for 14.300 is 392 inches. Multiply by .06 and we get 23.5 inches which is 23'6" and that's the length of my reflector.

So now with the math done, we proceed to erect that Cloudwarmer. Put up a dipole 16'4" from either side of the center insulator and feed it with any length of, for example, RG8U. Take an SWR reading and WRITE IT DOWN..it's VERY IMPORTANT.
Next, string out a relector wire about 10 feet below and about 2 feet LONGER as parallel as possible. Each end should terminate in insulators. There is NO ELECTRICAL CONNECTION between it and the driven element dipole nor is there any electrical connection between it and the coax feed. It just hangs there minding its own business but is nevertheless the secret to success!

Now take an SWR reading with everything in place. If you see ANY change whatsoever, good or bad, LEAVE THE INSTALLATION ALONE! It's working! If there's no change then either LOWER the reflector 6" at a time or LENGTHEN it by a few inches. What we MUST see is a change in that SWR. Once it happens, go work the world and YOU WILL.

We know that a dipole less than a full wavelength high has a multilobular pattern with appreciable ground loss. Now when we use a vertical at ground level, we must add radials. Why? Because we must minimize ground loss. The radials are RF collectors meaning that the emitted RF instantaneously is picked up by them and RETURNED to the base of the vertical to be RERADIATED at about 15 degrees to the horizon. That reflector acts just about the same way. It MINIMIZES ground losses by reradiating the RF into the "clouds" at much higher intensity than will a standard dipole and your signal will be heard in places you never knew existed. The Cloudwarmer has APPRECIABLE gain on receive versus a standard dipole and vertical-REMARKABLE GAIN. And on transmit, try switching back and forth between it and another antenna and see what happens. The person on the other end will be STUNNED!

5209. Re: 40-Meter Vertical Dipole

Message-ID: <99129d$i1t$1@nntp9.atl.mindspring.net>
Source record: 168083

I have a short Mor-Gain Dipole (66') for 80 and 40 mounted almost vertical
from a rall tree branch. It actually slopes 20 degrees
on the ground side end. The pattern is nearly omni with slight directivity
toward the east (NOT GAIN!). The end is about 12 feet
off the ground. ANY horizontal dipole or inverted V willl work better for
short skip (within 800 to 1000 miles) but where it comes to the fore
is DX as it has a low angle comparable to a vertical. This antenna worked
D68C on one call on 75 SSB.

Why would that be, Steve? Is it not heat because it is confined to a narrow band
of frequencies rather than having a black body spectrum? Is the shape of a signal's
spectrum the determining factor in deciding when radiation is heat and when it is not?
I don't think so. The principles don't change with frequency.

From our provincial viewpoints, we often want to confine heat radiation to the infrared,
because we can sense that directly with the nerves in our skin, but there is no principle
which requires this limited view. All radiation is thermal in the sense that it can agitate
matter when it encounters it. Low frequencies just don't do it as vigorously as higher
frequencies.

Energy radiated from a point source *is* dissipated throughout space, whether that
point source is a candle flame or an amateur radio antenna. Dissipation is energy
dispersion from the source in such a manner that it is irretrievable by the source in
the same form, IE entropy of the transmitting system increases. Except in the case
of a radar system, that describes what occurs with any radiating system.

Of course the energy doesn't cease to exist, energy can neither be created
nor destroyed (ignoring nuclear events for this discussion). It either goes
somewhere else, or changes to another form. But the key thing with
respect to dissipation is that the source can't get it back in the same form.
Resistors do it, antennas do it, infinitely long transmission lines do it. etc.
(Which is why we can treat all of them as equivalents in system equations.)

Gary Peach is right that all propagation is dissipative. If all the energy were
still available to the source, it couldn't be said to have propagated. Once it
leaves at the speed of light, nothing is fast enough to run it down and bring
it back. It is gone irretrievably.

Even if you do use signal processing, Shannon sets a hard limit at
-1.6 dB Eb/No. So when the signal power of any given information
symbol is -1.6 dB below the noise power in the matched bandwidth
used to convey the symbol, you've gone as far as you can go.

Nonsense. Lets assume an ideal diode for the sake of discussion.
If you attempt to measure the resistance of the diode, during one
half cycle, it will measure infinite, during the other half cycle it will
measure zero. At no time is it similar to the resistance of the light
bulb, which it would have to be for your "dissipationless resistance"
argument to be true. It doesn't work out if you try to average its
resistance either. Infinity plus zero divided by 2 is still infinity.

But for the sake of argument, lets assume the diode is a "dissipationless"
resistance. Then if we shunt two of these diodes in series to ground, we
should be able to measure half the supply voltage at the junction of the two
diodes. Do we? No we don't. Not ever, not even as an average. A pair of
equal resistances would show us half the supply voltage, but the diodes
don't, so we must conclude they aren't resistances, dissipationless or
otherwise.

If a resistance is a resistance, it must obey all the laws relating to resistance.
If it doesn't, it isn't a resistance. These diodes don't obey Kirchhoff's law for
series resistances, so they aren't resistances.

Hi Gary:

"Dissipation" infers that energy is lost in the form of heat. EM energy is converted to thermal energy. When an EM wave propagates away from an antenna, the energy density thins out as a function of distance traveled. This process (the rate of energy thinning) is identical for all frequencies. This is the basis for the derivation of the familiar path loss formula. At an infinite distance, the thinning process will cause the energy density to go to zero, but this is not a "dissipation" process. Dissipation of the energy will only occur if the energy encounters a lossy medium. The formula for path loss is written as a function of frequency because an antenna with a defined physical aperture extracts less total energy out of a passing wave with increasing frequency.

Message-ID: <3ab44dea.24383403@news.igs.net>
Source record: 168093

with the R5 ..there are some things to really watch for...make sure
the fiberglass base insualator is really clean and all the joints are
cleaned and properly treated with antioxidant
" i like..butternuts brand "butter-its-not". Keeping that base
insulator free of conductive trails on the inner side is particularly
important. I bought a used R5 once and couldnt get the SWRs
right..but after a thorough cleaning with alcohol throughout..it
behaved as per the graphs in the manual...73 Earl VE3AB
ps..if you ever have to fix the base where the aluminum main
radiator fits into the base insulator..that dimension is important..
if it is "slid in" too much..you'll get poor swr curves and i would
venture..poor performance.

Gary Coffman wrote:
"Nonsense."

A resistance is a ratio of voltage to curent in which the voltage is in phase with the current.
When current is flowing in a diode it is in phase with the voltage.

Given a perfect diode in series with an a-c circuit containing a resistive load, the perfect diode acts as a perfect switch which operates in synchronism with the applied voltage.

The power delivered to an a-c resistive circuit with no diode is peak voltage times peak current divided by two. Insert a diode and power is cut in half. The circuit is disconnected half the time. So, the power to the load will be peak voltage times peak current divided by four.

The effect on a resistive load over a complete cycle is the same on average as adding a series resistor in the circuit equal in value to the load. The temperature rise in the load will be the same either way the power is limited.

The temperature rise of the perfect diode will be nill because we`ve specified it is lossloss.

The temperature rise of the limiting resistor added to limit power to the same value as the diode does will be the same as that in the load resistance itself given a similar size shape, and surroundings.

So, with the diode limiter we have in effect a lossless resistance which is not a resistor. With the limiting resistance we have a resistor.

With the diode limiting the power supplied to the load, the power not wasting in a limiting resistance is not supplied by the source. The Class "C" amplifier and the switching regulator are among other devices using "lossless resistance" to current flow.

Best regards, Richard Harrison, KB5WZI

>electric energy as heat."

Then the IEEE Dictionary is illiterate.

Gary C has it right. As any normal dictionary should tell you, the key feature of dissipation is that something - no matter what - has been lost and dispersed irretrievably. You can dissipate money, you can dissipate goodwill, and you can dissipate energy of any form.

The only essential requirement is that it's a loss from the system you're trying to account for, and you don't know where it went. In the case of dissipated money, it's gone out of your possession and you don't know where to. In the case of electrical (RF) energy in a transmitter-feedline-antenna system, some is dissipated as heat but hopefully most is dissipated as EM radiation.

It is quite wrong of the IEEE Dictionary to identify dissipation of electrical energy exclusively as heat.

It is also wrong to claim that "radiated RF energy is eventually degraded to heat, somewhere in that universe." It is true, of course; what's wrong is that it's cheating on the system boundaries. Dragging the universe into the argument is like saying, "I've dissipated all my money, but it must be out there somewhere..." - and just as pointless.

In any system smaller than the entire universe, we have to draw a boundary round it in order to analyse it. But then we must keep that boundary fixed, all the time. If we don't, the results of the analysis are going to be nonsense.

Power station engineers have a very clear sense of their system boundary - it's the perimeter fence. They account for their own energy inputs and losses on site, but their analysis ends with "watts sent out" to be dissipated by customers outside the fence. You won't catch a power station engineer wondering about that energy being degraded into heat

throughout the universe.

Likewise in an engineering analysis of a transmitter-feedline-antenna system, we're considering only the energy flows in the wires. Anything that isn't electrons flowing in a wire, is outside the system boundaries and not part of the analysis. Inside those system boundaries there is an exact balance:

(electrical energy supplied to transmitter) = (RF energy dissipated by EM radiation) + (energy dissipated in other ways, almost entirely heat)

The point about dissipation outside of the system is not that you shouldn't consider where it has gone - it's that you MUSTN'T.

5223. continous/linear loading

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-18 11:51:04 UTC
From: Maurice Murphy <Maurice20@btinternet.com>
Message-ID: <9928bnfrs1@plutonium.btinternet.com>
Source record: 168097

On the subject of so called meander dipoles and monopoles , they are really lumped continous loading of course. They do raise some very interesting questions and experiments galore have been going on at this qth.
I have constructed many dipoles and monopoles for
many different frequencies and also used meanders at different positions in a radiator in an effort to produce some sort of formula to predict the behaviour of an aerial wire loaded in this manner.
So far it would seem that given a constant area the
wavelength of the loading section increases by the root of the decrease in spacing. Meander sections also behave in the same way as inductors in that the wavelength absorbed is greater in high current areas.
As you mention I must point out that the feed point
of a resonant meander system (i.e. the centre in the case of a dipole)is not a current antinode. A full size loop aerial is a simple example of this principle as its perimeter exceeds one wavelength.
Come on gents lets hear if you have similar views.

"Then the IEEE Dictionary is illiterate."

Often there is more than one dictionary definition of a word. The definition to be used depends on how and who is using the word.

Ian is correct in saying: "You can dissipate money---". But the IEEE definition includes in paranthesis the words (electric energy) meant as a restriction of the definition to how it is used in the electric energy industry.In the industry among technical people it does not mean money irretrievably lost, and it does not mean electrical energy radiated from an antenna or anything else. It means electric energy converted to heat.

For whatever it's worth, when I was a kid I put up a 40 meter ground plane.
About 33 feet of aluminum tubing, ground-mounted, sticking straight up. With 4
or 5 buried wire 1/4-wave radials, running every which way. Used a Heath AT-1,
putting out about 15 watts, cw.

It did okay within a few hundred miles, but I only made one cross-country
contact.

I probably needed more radials. Or more power.

I agree.

RF energy radiated into space is not dissipated, it is "dispersed" in its original RF form. The fact that some of that energy can be recovered in a distant receiver proves that it is not "dissipated" (converted to heat).

The IEEE had in mind this specific idea. They are not "illiterate", except to those who disagree for whatever reason.

IEEE bashing seems to be a pastime.

Outside the earths atmosphere, the solar constant is 1384 W/m^2. The
actual value varies slightly with variation in the Earth - Sun distance
and solar activity. For many purposes such as calculating the output
available from a photovoltaic array, the spectrum can be considered to
be that of a blackbody at a temperature of around 6000 K.

I wrote:
"So, that gives 46.9 watts per square foot into the cell or 505 watts per square meter."

I discovered a glossary in the solarex book. It says: "AM 0" indicates that there is no atmosphere in the path of the light. This is the condition out of space where the power density is about 136 mW/cm squared."

Let`s see, 10,000x136mW is 1360 watts per square meter.

It also says: "AM 1" is the condition at the surface of the earth where the light passes through one atmosphere. The power density is 100mW/cm squared."

That would be 1 KW per square meter on earth.

So, it seems we have a two to one contradiction within the same little book. I have no explanation.

Best regards, Richard Harrison, KB5WZI

Roy, I hope you're statement above was intentionally cynical, because that's
the way I interpret it. I consider a " time-varying electrostatic field" an
oxymoron. Do you really mean you 'stand corrected'? Or have you become a
stand-up comedian? (Pun intended)

Yeah, and don't the fields cancel when you reverse the direction of the
petting? And without a Faraday shield yet!

Ian:

Energy radiated by an antenna is not "dissipated". This would infer that the energy was traveling in a lossy medium and was converted from one form to another.

Energy radiated from an antenna is dispersed in space. It simply travels away from the source. The energy density decreases with distance because of the dispersion process not dissipation.

The energy radiated by the antenna is not "lost" as you imply. If the energy was "lost" through dissipation it could never be recovered. In theory (this is impractical but it illustrates the point), if you could surround the antenna with a sphere capable of collecting all energy hitting the sphere, all of the energy radiated by the antenna could be recovered at any distance away from the antenna. The only time this would not be true is if the energy encountered a lossy medium as it traveled.

Steve

>The IEEE had in mind this specific idea.

If I may reply to Bill and Richard together... sorry, I still can't accept conversion to heat as the exclusive definition of "dissipation" in the context of electrical and electronic engineering.

Bill's contention that RF energy radiated into space is not dissipated does not stand up to examination. Other than in radar, RF energy that has been radiated by a transmitter-feedline-antenna system is not recovered BY THE SYSTEM THAT RADIATED IT. Pardon my shouting, but the whole thing is about drawing the correct boundary around your system. When you analyse the DC to RF power conversion in your transmitting station, you never in fact consider the tiny fraction of the RF energy that might be received at the other end - because that is beyond the boundaries of your analysis.

To examine in more detail what Bill said:
>The fact that some of that energy can be recovered in a
>distant receiver proves that it is not "dissipated" (converted to heat).

On the contrary, it's easy to prove that 99.several-nines% of your radiated RF energy is indeed converted to heat. For example, if you transmit a 1000W signal, and a million receivers receive a picowatt each (7uV in 50 ohms) then only 0.0000001% of your radiated RF energy is ever "recovered". All the rest will converted to low-grade heat, somewhere in the universe. Therefore Bill's example only helps prove my point: once the RF energy has left your transmitter, it is totally dispersed to destinations unknown... and the word for that is "dissipated".

> They are not "illiterate", except
>to those who disagree for whatever reason.
>IEEE bashing seems to be a pastime.

It is certainly not my habitual pastime. I generally respect technical dictionaries, because the definitions have usually been examined at grat length by committees of very picky people. If such a definition looks strange to me, I always examine my own thinking first.

So I did - very carefully - and fully accept that conversion to heat is *one* valid use of the term "dissipation". What I don't accept is the implication that conversion to heat is the *only* valid use of the term in electrical and electronic engineering.

Sorry, Steve, but it's you who are inferring that.

We were trying to analyse what happens in the conversion of DC to RF
within the transmitting station. Within the boundaries of that analysis,
we do not know what happens to RF that is radiated - and more
importantly, we are not allowed to ask.

By considering how the RF energy travels through the propagation medium,
you have shifted the boundaries of your analysis and are now analysing a
different, extended, system.

>Energy radiated from an antenna is dispersed in space. It simply travels

I understand and agree with all of that, but in the analysis of a
transmitting station, any discussion about RF propagation is outside the
original boundaries of the problem, and therefore inadmissible evidence.

IMO a good engineering definition of "energy dissipation" is
"irreversible transfer of energy beyond the boundaries of the system
under consideration." That includes the IEEE definition as a subset.

Hi Achmed,

Most of my designs are vertical monopoles so that I can leverage the complexity of design against a perfect ground. Thus, by abstraction,

they are dipoles. If this is acceptable, then you might try:
http://members.home.net/kb7qhc/antenna/fractal/index.htm

I have quite a backlog of other designs that are dipoles. The
following link shows the progressions of iterations for a triangle
sweep that is dipole in nature:
http://members.home.net/kb7qhc/antenna/fractal/Triangle%20Sweep/index.htm

Another design that I offer as a practical one (I am not interested in
practicality by and large - this field defies that from the get-go)
also meets your interest in dipoles:
http://members.home.net/kb7qhc/antenna/fractal/InVfracV/index.htm

The boundaries of the "system" must go beyond the transmit station. To understand the process of radiation from an antenna and the resulting propagation to the recieve system (dispersion), we can't simply limit our boundaries to the transmit station and then declare that all the energy that left is "dissipated".

Because you "do not know what happens to RF that is radiated" is exactly why your definition of "dissipation" is incorrect. All you know is that the energy is radiated from the transmit system. If you do not want to look beyond the boundary of the transmit station then your discussion should stop at "radiation".

As stated above, your discussion should stop at the concept of radiation. Your statement that "any discussion about RF propagation is outside the original boundaries of the problem" would also preclude you from stating that the energy outside your boundary is "dissipated". All you know is that the energy is outside of your boundary and you should not discuss further.

Unless you are willing to look beyond your boundary, you should not challenge those who do.

One is certainly entitled to one's opinions. My opinion is not the same as yours. I agree with the "illiterate" IEEE. My opinion stands up to my examination (and the IEEE's) just fine.

Radiated electromagnetic waves can travel virtually forever, for example galaxies that exploded 5 billion light years ago. There is a satellite telescope that is now measuring the X-rays from their black holes.

>once
>the RF energy has left your transmitter, it is totally dispersed to
>destinations unknown... and the word for that is "dissipated".

"Dissipated" is your word for it and that is OK for you. My word for it is "dispersed" and that is OK for me. But they are not the same thing.

The space beyond a free-space (for example) antenna is a transmission line. The antenna is a "transducer" from the 50 ohm line to the 377 ohm line. Space is nothing more than an "extension" of the physical antenna. The total electromagntic energy is essentially the same everywhere, near or far. The beam pattern in free space is exactly the beam pattern that the antenna gives it. To think of that process as dissipation is strange and contrived, in *my* opinion.

In my opinion the illiterate IEEE and (presumably) the illiterate IEE know what dissipation is and what dissipation isn't.

And as for the other 99.9999% that you mentioned, are you sure you know (and how do you know) what is happening to it? If all of it is being picked up, is any of it dissipated? If no one hears it is is all dissipated? Does dissipation really depend on how many receivers are tuned in? I believe you have a logical dilemma regarding "dissipation" in this context.

Bill W0IYH

5247. Balun location on LPY

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-18 20:07:41 UTC
From: "Peter J. Bertini" <commquart@home.com>

Source record: 168121

My Log antenna instructions recommend placing a balun at the feedpoint; but I am wondering if the the balun wouldn't be better if placed at the mast plate.. My thinking is with the coax being strapped to the lower boom a lot of energy would be capacitively coupled to the shield; thus defeating whatever was gained by having the balun at the feedpoint.

Where is the best place to put the balun, and what would work best on a 13 to 30 MHz design; ferrite sleeve or coaxial loop?

Thanks

Pete

If we don't agree on definitions then communications is impossible.
What higher standard exists than the IEEE dictionary?

The term "electrostatic capacitance" refers, as a matter of convenience, to the ratio of charge to voltage in a *physical* capacitor. This C is thus distinctive from the C of free space, which is associated with EM waves. In a shielded loop, "static" C is the actual, physical capacitive coupling from a nearby object to the loop that is inside the Faraday shield. It's just a matter of convenience that Terman uses. Nobody is confused.

In the case of the loop antenna, it is helpful to use a literary device of this kind to avoid ambiguity.

The IEEE dictionary allows another valid definition of "dissipation -
(2)(waveguide) The power reduction in a transmission path caused by
resistive or conductive loss, or both."

Well, if we set the boundaries as the universe, would you agree that
some RF that escapes the atmosphere of the earth is not dissipated
until the next big bang?

It's not a dictionary of the English language, Richard, it is a
dictionary of technical terms. Presumable, "heat" is not a technical
enough term to be included in a dictionary published by the Institute
of Electrical and Electronic Engineers. They don't have a definition
of "as" either.

Source record: 168139

Yes you're quite correct, the radials attach to the bolt holding the lower end of
the coil. The coil is mounted across the insulation between the antenna and the
ground post. If the existing coil is corroded, it is very easy to wind a new one.
Be very sure that you only use stainless steel hardware to bolt the top and bottom
of the coil onto the HF6V.... be very careful not to let copper come into contact with
the aluminium of the antenna or ground post. The interaction between copper and
aluminium is dreadful and you will find the electrical connection deteriorates very
rapidly. So I would suggest having at least one stainless steel nut between the
copper of the coil and the antenna.

If you are putting the radials on, or under the ground, the length of the radial does
not have to be resonant as the ground will detune the things. The secret is to put
as much metal on or under the ground around the antenna. Remember that a lot of
short radials produce better results than a few long ones, a lot of long ones is even
better.

My experience with the HF6V over the last decade is that it is the best HF vert
around however, I have always ensured I have a good ground return path for
the RF, either radials or where that was inpractical then I've used a mat of chicken
wire around the antenna.

Please excuse me if I'm telling you things you already know.

Don't expect miracles on 80M or even more so on 160M if you consider
purchasing the additional coil., even from the HF6V,as Butternut say in
their literature "they can't beat the laws of physics".

As for the WARC band coil pack, my experience is that it degrades the performance
of the antenna overall, but perhaps I was unlucky.

If you've inherited a 75 ohm matching section then I'd consider renewing it
and
also any feeder that may have come with the antenna.

Finally ensure you go with the instructions about a decent DC earth
rod/rods,
these won't help much/at all, as regards RF performance but will help ground
static electricity.

Good luck with the HF6V, look after it and it will return your care with DX
that
the other guys with ********** verticals won't work.

73 Tony G 3 Z R J
the HF6V is a very short radiator on 80 and 160

I think it is strictly true that heat is always associated with molecular
motion, but electromagnetic radiation is a mechanism for heat transfer (the
other two are convection and conduction). If you run a current through
a resistor in a vacuum then virtually all the electrical energy the
resistor consumes will be transfered away from the resistor in the
form of electromagnetic radiation, some of which may never find other
matter to interact with and may hence travel forever. By your definition
wouldn't that make the resistor dispersive, but dissipationless?

>And as for the other 99.9999% that you mentioned, are you sure you know (and how
>do you know) what is happening to it? If all of it is being picked up, is any
>of it dissipated? If no one hears it is is all dissipated? Does dissipation
>really depend on how many receivers are tuned in? I believe you have a logical
>dilemma regarding "dissipation" in this context.

I'm also not sure why the ability to detect and measure energy would
preclude that energy from having been dissipated by its source. I have
no trouble detecting when my furnace is dissipating chemical energy as
heat, so I'm not uncomfortable with the idea that my radio receiver
detects energy that was dissipated by someone else's antenna.

VE9SRB <srbest@att.net> wrote:
>Energy radiated by an antenna is not "dissipated". This would infer that
>the energy was traveling in a lossy medium and was converted from one form
>to another.

The IEEE definition for dissipation was the conversion of electrical
energy to heat. Electromagnetic radiation is a mechanism for heat transfer
(the only mechanism that operates in a vacuum, the other mechanisms
are convection and conduction), so by the IEEE definition it would
seem that the energy was dissipated as soon as it left the antenna
in the form of electromagnetic radiation.

In fact I'm not entirely sure that the above is true, but what I am
sure of is that any argument that electrical energy isn't being
dissipated into electromagnetic radiation by the antenna has got
to involve the coherence of the resulting radiation. Other than
its coherence, the electromagnetic radiation emitted by an antenna
is indistiguishable from any other radiated heat.

>Energy radiated from an antenna is dispersed in space. It simply travels
>away from the source. The energy density decreases with distance because of
>the dispersion process not dissipation.

So, if I run a current through a resistor in space (i.e. a vacuum), does
that fact that all the energy consumed by the resistor is radiated
away from the resistor as electromagnetic radiation now mean that
resistors in space aren't dissipative, but rather are simply dispersive?

There are no processes where energy is not conserved, so suggesting that
a process is not dissipative because it is energy-conserving implies that
no process is dissipative. When I was in school processes which were
energy-conserving (all of them are) were still dissipative if they
produced entropy. People often say "conversion to heat" when they
mean entropy production, but in fact dispersive processes of any
sort generally produce entropy even if they don't involve an energy
conversion at all. For example:

>The energy radiated by the antenna is not "lost" as you imply. If the
>energy was "lost" through dissipation it could never be recovered. In
>theory (this is impractical but it illustrates the point), if you could
>surround the antenna with a sphere capable of collecting all energy hitting
>the sphere, all of the energy radiated by the antenna could be recovered at
>any distance away from the antenna. The only time this would not be true is
>if the energy encountered a lossy medium as it traveled.

Here you again argue that radiation isn't dissipative because energy is conserved, yet all processes conserve energy. Dissipation isn't associated with energy conservation (energy is always conserved), it is associated with entropy production, and the process you describe above appears to me to be entropy-producing.

Here is an analogy. I have two perfectly insulated buckets containing 10 kilograms of water, one at 60 degrees above ambient temperature and one at ambient temperature. If I have a thermometer to measure the temperature above ambient, and a scale to weigh each bucket, I can tell you how much heat energy I have in each bucket. The bucket at 60 degrees above ambient has heat, the one at ambient temperature has none.

I now mix the water from each bucket. After they mix (i.e. convective heat transfer), I measure the temperature and weight and discover that the total amount of heat in the mixture is identical to the total heat energy in the buckets I started with, with the 20 kilograms of water now being 30 degrees above ambient. Energy is conserved, but the heat that used to be in the one bucket is now distributed over twice as many molecules and the temperature is halved. But while the process is energy-conserving it is dispersive, and hence entropy-producing, and hence is dissipative. That is, no process can be designed which will have the sole effect of separating the water back into two buckets, one at 60 degrees above ambient temperature and the other at ambient temperature, even though the latter process would also conserve energy. The process has done no energy conversion, but it has transformed the higher-grade 60 degree heat into lower-grade 30 degree heat, which is irreversible and hence dissipative.

The same applies to your example above. The energy density very close to the transmitting antenna might be many W/m^2. If you'd closely coupled a receiving antenna to the transmitting antenna such that no energy was radiated (i.e. if you'd built a transformer) you could have recovered the electrical energy in its original form, but if your surrounding sphere is large enough to be collecting radiated energy you'll be collecting the energy at energy densities of mW/m^2 or uW/m^2 or less. This process is entropy-producing (i.e. there is no process you can design which has the sole effect of returning the energy captured by the sphere to the W/m^2 form it was in when it left the antenna), and is hence as dissipative as any other form of heat transfer. Dispersive processes are synonymous with dissipative processes, as far as I can tell, and the process you describe above is identically a dissipative, entropy-producing transfer of energy from the antenna to the sphere.

Cecil, W6RCA wrote:
"From the IEEE Dictionary: "dissipation (electrical energy) loss of electric energy as heat."

My Random House Dictionary gives (5) definitions, none relate directly to (electrical energy). There are other dictionaries devoid of definitions of dissipation as applied to electrical energy. That`s why the IEEE definition was especially worthwhile.

Here are "Dissipation" definitions from my dictionary:
(1) Act of dissipating.
(2) State of being dissipated; dispersion; disintegration.
(3) A wasting by misuse.
(4) Mental distraction; a diversion.
(5) Dissolute mode of living; intemperance.

The power fed an antenna system is either radiated as a radio signal or converted to heat on-site. We consider heat as wasted energy (dissipation) and radio waves launched by the antenna system as useful because that was our purpose. The launched radio waves are not wasted by misuse, not a diversion, nor dissolute.

I think IEEE got the definition of dissipation just right.

Best regards, Richard Harrison, KB5WZI

>an infinite distance, the thinning process will cause the energy density to
>go to zero, but this is not a "dissipation" process.

I don't see how this could possibly be true. Radiated EM energy *is*
heat in the process of being transfered, and all heat transfer is
dissipative (i.e. generates entropy). In fact, while there are other
heat transfer mechanisms that can operate when you have sufficient
mass density, in the end all heat ends up being transfered in the form
of EM energy. The bulk of the heat generated by hydrogen fusion
at the core of the sun is transfered away from the sun in the form
of EM energy. If you go outside on a sunny day you will indeed
find that heat is being transfered to the molecules on the surface
of the planet in a form we're more likely to call "thermal energy",
but even that is reradiated into the night sky as EM radiation again.
EM radiation is heat in the process of being transfered from a
warmer place to a colder place, and this is the most fundamental
definition of "dissipation".

Irreversible processes are dissipative processes. The decrease in
the radiated energy density, and the resulting reduction in thermal
energy which can be extracted from the field by individual molecules,
is "dissipation" whether the EM energy actually finds molecules to
transfer the thermal energy to or not. And even if it does find
molecules, the molecules themselves will simply re-radiate the
heat as EM radiation again so finding those molecules is not
going to decrease the flux of radiated EM energy either. Energy
is always conserved, this has little to do with dissipation.

The only difference I can see between EM energy radiated from
an antenna and general radiative heat transfer is the coherence
of the energy radiated by the antenna. I'm not sure this matters,
but I am pretty sure that any argument which distinguishes between
EM energy radiated from an antenna and general radiative heat
transfer has got to be based on coherence, since there is no
other difference that I can see.

5276. moved cordless phone's antenna to the top of the hill

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-19 05:57:30 UTC
From: Dan Jacobson <jidanni@kimo.FiXcomTHiS.tw>
Message-ID: <m2snkal2r9.fsf@dan.jacobson.tw>
Source record: 168055

In order to increase coverage to the backside of the hill, I have removed the antenna of my cordless phone's base unit and instead attached a coaxial cable 40 meters long to the middle of a stainless steel thin hollow pipe 4 meters high placed vertically on top of the hill, next to a taller grounded pole that will hopefully attract lightning instead.

Seems to indeed have increased coverage. My question is how about the shielding of the coaxial cable? Should I ground it at one end, both, or what? The pole itself: currently not grounded to anything, held in place by wood. is this good? Is the middle of the pole the most ideal connection spot? Is pole length critical? [Seems about twice the length of the original antenna but I didn't bother to measure it.] Yes this is just a simple 250 meter range home cordless phone.

While we're at it, the hand unit's antenna got one section bent off. How critical is having the original length or the simple fraction of the wavelength for cordless phones? I see mostly one uses them with antenna folded in anyway.

To avoid banging into trees and brush with the hand unit's original antenna when extended, can I instead attach a flexible wire, say in my belt loops, or would a non straight antenna like that be ineffective as an antenna, [especially with me in the middle]? If I get a call I can always extend the original antenna, or hold the wire taught, while talking. Is it bad for such wires to be next to one's body?

5277. 23 cm superturnstile antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-19 06:30:29 UTC
From: "J.F. FOURCADIER" <jf.fourcadier@wanadoo.fr_NOSPAM>
Message-ID: <99490j$jc8$1@wanadoo.fr>
Source record: 168151

Hello !

Presently, I build an ATV repeater with some friends and we are looking for an antenna horizontally polarized with an omnidirectional radiation pattern. The equipment is going to operate in the 23 cm band and a high gain is obviously highly wishable.

I have seen descriptions of the Alford slot antenna which has a medium gain and would be suitable, but commercial TV stations often use superturnstile antenna which have more gain.

Does someone hear of homebrew superturnstile antenna for the 23 cm ham band or other high gain antenna ?

Thank you for your help.

Richard Harrison wrote:

> Cecil, W6RCA wrote:
> "From the IEEE Dictionary: "dissipation (electrical energy) loss of
> electric energy as heat."

In electrical engineering, *common usage* of the term "dissipation" is well understood to mean the conversion of electrical energy to heat. This has been understood in the engineering world for at least a couple of hundred years. It is deeply ingrained into our engineering culture.

This may not conform to the usual dictionary definitions, in which "dispersion" is included. But when someone tells me the dissipation of an electrical system, my experience and my IEEE dictionary tell me exactly what is *intended*.

According to an ordinary dictionary, radiation (dispersion) from an antenna can be construed as "dissipation". However, since energy is not in any way converted to some other form, it does not fit the tacit understanding of what we techno-folks think of as dissipation.

We often find ourselves splitting hairs over semantical matters like this. I believe that the IEEE idea is consistent with common usage, and as such is not the least bit "illiterate".

When we talk about the power "dissipated" in an antenna we know exactly what we mean: the power dissipated in the wire and transmission line, not radiated.

And, Ray, Dave's mention of a "similar" antenna is what prompted my reply to him. The book that has that antenna is the Vertical antenna book written by W6SAI - believe his name was Bill Orr???

I've got it at home and had it sitting out to bring in today but - didn't; another example of CRS setting in! I'll have it here tomorrow to pass on to Dave as it has discussions on several antennas that are similar to that old Gotham thing.

That Gotham worked about as well as a wet noodle did. However, back then I was 12 to 14 years old and didn't know a radial from a radio - or something like that. My exposure to antenna theory and construction was extremely limited, as opposed to today where it's merely limited - LOL!

Yep, all dem radials and the tuning done at the antennas base make all the difference in the world.

For Dave: I'll have that book info tomorrow A.M. Regards, Jim R.

"R. Makul K1XV" <k1xv@arrl.net> wrote in message news:06e5bto2hekhdtajdkp8gip6uh3o5c05bq@4ax.com...
Jim: I did read it. Dave's primary goal is to build a REPLICA of a Gotham Vertical based on its original specifications, or plans for a SIMILAR antenna.

Jim, to me, a replica to a Gotham Vertical means one that is a simple multi section thin wall aluminum tube end fed through a B&W inductor at the bottom, attached to the hot side of an unbalanced antenna coax via an alligator clip so you can vary the inductance by changing the tap location on the coil with the alligator clip. The ground side of the coax attached to a ground rod. The whole thing then attached to the side of a house or to a non conducting support via "u" straps.

I agree that the ARRL books have discussions of verticals, but I never saw anything in there that was quite like a Gotham Vertical as I have described it, but I may be wrong. I often am.

Anyway, its not worth getting worked up over. Everybody seems to want to help somebody build something that works, but I think Dave wants to build a replica of a Gotham Vertical for "historical examination", regardless of whether it would or wouldn't work, to check for himself exactly how accurate or exaggerated those old advertisements were.

Just wondering Jim, in retrospect, how well did that Gotham work? I suspect your present vertical, with radials and a much more sophisticated loading system, works much better.

Everybody have a Happy St. Patrick's Day!! ;^)

About glass mount antennas. Apparently there is a substance called passivated glass that is used on some autos. Radio Shack for one warns against using a glass mount on this windshield. Some info on glass mounts and tinted glass at URL:
http://forums.vmag.com/suvtahyuk1099/messages/5991.html

From URL:
http://www.alternativewireless.com/cellular-antennas/antennaFAQ.html

"Can I install a glass mount antenna myself?
Since glass mount antennas are glued to your cars glass (making them a non returnable item) and the antennas cable is a little harder to run inconspicuously through the car's interior, we highly recommend professional installation of glass mount antennas. You also need to consider window tinting, defroster wires, proper placement, and passivated glass (glass impregnated with tiny metal particles that render the glass incapable of coupling RF between the inside and outside couplers).

How can I tell if the glass on my vehicle is suitable for one of Larsenï¿½s on-glass antennas?
First, look near a corner of a window for words that mean "sun", relate to sun, or refer to ultraviolet or other forms of radiation. If you find terms like "Soft-Ray", "EZE-Cool", "Solar-Coat", "Solar-Cool" or similar terms, your glass is probably passivated and wonï¿½t work with on-glass antennas. If you want to be 100% certain, and you donï¿½t find helpful words on the glass, ask a 2-way or cellular shop technician to test your glass with a capacitance meter."

Some folks here have had trouble mounting them on the rear window (away from ignition noise) where the defroster wires can interfere with the installation.

On the other hand, one of our locals here has used them for years and prefers them to mag mounts and sez they work fine.

Also use google.com -- type in "glass mount antenna" and get lots of
sites that discuss these antennas.

You can see light. You can feel heat. Some of the other radiation makes no sense.

If I had a big enough "Thermos Bottle" could I store radio waves for long periods? Would it need a vacuum space to prevent conducton and convection? Seems there are practical differences, at least on a human scale.

If they buy an axe, they should use it on the CFA...or better yet on
the people who sold them the CFA.

Then they can use the regular antenna, and get the old signal back.

Yopu are right Peter. Tennadyne (I think that is who it is) tells
people to put the balun AT THE WRONG SPOT!!!!!!!!!

I ran into that with a friend of mine.

The balun belongs at the point where the feedline exits the lower
boom, NOT at the feedpoint!

Use a coaxial choke balun at the point where the cable leaves the
lower boom, and simply tape the cable to the lower boom out to the
end. Connect the shield to the lower boom and the center to the upper
boom.

If you put the balun where they tell you, the balun won't do a thing.

Source record: 168164

Peter- Rohn uses a four guy system on the fold-overs to make clearance
for the boom. The Rohn instructions call for a guy on each of the legs
that dont have the boom, and two guys attached to the bracket at the
hinge point on the boom leg. If you try for three guys, you must make
allowances for clearance for the boom to tip up, which means an angular
offset, which means trouble.
Actually, the four guy system works well for me- the distance to the
anchors is less than for a three guy system.

Bill,

I found that a delta with the apex at 75' worked well both locally and
for DX on 75m. It was cheap (I already had the tower up) and quiet; I
managed ZL and VK with it (plus 50 states and some south americans) so
I can't complain.

Then Bill is dependoing on near vertical incidence sky wave propagation. Ground wave propagation ranges from poor to very poor at h-f. It is almost none for horizontally polarized waves. Ground wave propagation gets worse as frequency rises for both polarizations.

For "close in work" the near vertical incidence sky wave works. Vertical radiators have a null at the zenith. See Fig 16 on page 3-13 of the latest ARRL Antenna Book. So, the vertical radiator is not a good antenna for near vertical incidence.

The horizontal antenna is a good radiator at high elevation angles as needed for near vertical incidence when it is erected at low heights. See Fig 12 on page 3-11 of the new ARRL Antenna Book.

35 feet is 10.67 meters or about 1/4-wave at 40m. The high angle radiation is good. At 1/2-wave above ground or or the 20m band, the vertical radiation is down some but radiation at lower elevation angle radiation is up and that is good for more distant contacts.
Best regards, Richard Harrison, KB5WZI

5298. Bicycle antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-19 16:26:46 UTC
From: wsmith@cinci.rr.com
Message-ID: <3ab63150.13092381@news-server>
Source record: 168167

I need a little advice about mounting an antenna on the rear of my bike. I have used a Diamond 770 series dual band antenna on other bikes with very good sucess. However, I have a new recumbent bike that is giving me a little pause for thought. I have a couple of pictures of the bike at:

http://albums.photopoint.com/j/AlbumIndex?u=1025520&a=12162755&f=0

On my other bikes I had a simple bracket to hold the antenna at the rear end of the rack. But, as you can see, there is an aluminum upright now in place to hold the cold weather/streamlining fabric. My question is: If I mount the antenna bracket on the rack, what problems am I going to run into with the close proximity of the upright. I would think the maximum distance that I can separate the two is about 4 inches. I am running almost exclusively 2 meters.

Thanks for any help.

Each discipline has its own vocabulary. Every person who has
studied electronics for any length of time knows what an
author of electronics texts means when he uses the word
"dissipation." "Dispersion" also has a special meaning.
David K. Cheng in his book "Field and Wave Electomagnetics"
writes, "The phenomenon of signal distortion caused by dependence
of the phase velocity on frequency is called dispersion." Calling
energy radiation from an antenna dispersion might cause some confusion.

Still rather have the dipole in most cases. The "remote areas" in the SW
are still too close together to use a vertical.
On 75m, I would use a vertical for dx only. But I don't chase much dx on
75m, so I don't use one. Also I don't have the radial room to put up a
"good" 75m vertical. Same problem on 160m. MK

This is incorrect. The impedance of the shield is not the same as the loop it shields, because it is
NOT a loop; it is open at the center.

> That's because the outer conductor becomes the actual antenna. We
> can't change that, because one the shield is several skin depths thick

Because the outer shield is several skin depths thick, the local E-field does not penetrate it.

> If you short the electric field, you are shorting the desired signal
> as well. They are inseparable.

Since I can short the local E-field and still receive a signal, this statement is also incorrect.
There is nothing sacred about 377 ohms, and the ratio between E and H fields can be quite a bit
different near an antenna. Indeed, by reciprocity, merely placing an antenna in a field creates a
near-field condition in which the E and H field ratio changes drastically.

> A broadcast FSM is calibrated to measure the electric field, and it often has a "shielded loop"
> antenna. Despite using a shielded loop, a FSM can indicate the electric field because it is
> INSEPARABLE from the time-varying magnetic field.

I am using an E-field meter. Not a loop. It uses a probe antenna sensitive only (at broadcast
wavelengths, certainly) to the electric field.

> You can change the field impedance or modify the direction of the
> field, but if you take the electric field to zero the magnetic field
> must go to zero. In essence, the structure becomes the antenna.

The structures of which I speak do not present a low impedance to a magnetic field, and consequently
do not affect it as much as they do the electric field. They do present a low impedance to an
electric field, and so, reduce it more than the magnetic field. As does the loop shield. Zero? No,
perhaps not, theoretically -- but theoretically we can have a point source radiator, which

cannot
exist physically. Not zero then, but a good 60 dB down, and maybe more.

My results imply your understanding is incorrect. What do your measurements show?

This criticism from a man who did not have enough motivation to join the ranks of amateur radio through the time honored method of earning his ticket. And he constantly criticizes amateur radio and much of its volunteer work and workers as if it and they are useless; unwanted and pitiful. This man is not a true amateur radio operator...he is one of the freebanders; a welfare wannabee! He exists, therefore he deserves whatever he wants! He is the one who has nothing of which to be proud. It seems the only thing he has is his mouth; which he visits upon us incessantly!

Yes. This dispersion effect is well known. It exists in signal processing systems of many kinds. One example is the "group delay" effect in filters.

Yes, there is a transmission line condition for a distortionless line that doesn`t discriminate against frequences and waveforms aren`t affected by the line except perhaps some loss in amplitude, and all frequencies have the same delay. It is called "Heaviside`s condition for the distortionless line":
R/L=G/C
Zo will be a pure resistance.

> http://www.mindspring.com/~w6rca

Cecil, Dick is not complaining about Techs as a group nor am I. We are reaping the results of fundamental dishonesty. I will give you two points to look up in your Funk & Wagnalls.

Point 1. The Tech is not and never was designed to be the entry-level license for HF amateur radio. It predates the codeless arguments so we can dispense with them. It was designed to serve a multiplicity of uses, all worthy but none of them in the mainstream of Amateur Radio. Some of them included:
a. Real honest experimenters - all 12 of them.
b. Wives wanting contact with the old man. The Bread-and-Milk thing which was the subject of a lot of dubious subterfuges of which I was once a major instigator. Every wife on our repeater was named Sally and had the same callsign, a 2x3 I once had for 2 months or so.
c. Personal communication of the type you describe with your camping buddies. The FCC whatever else one may think of them has a habit of encouraging communication. Good way to keep tabs on number one son when he is armed and dangerous on a hunting trip.
d. Taking some pressure out of CB. The spots were up then, too.

Without beating the point to death, selling the Tech as an entry-level ticket was and is fundamentally dishonest. In my VE days I did not administer them because I did not believe I was doing anyone a favor. As a practical matter I would not be called upon to anyway because of the necessity to keep the Advanced VEs occupied. In the context where Leland butted in, the discussion was advising the newbie. Guess what? I don't recommend taking Element 2 as an initial step either.

Point 2. This dishonesty, as lies have a habit of doing, has come back to haunt us -- certainly in the general environs of Newington CT. The Tech since it came into existence has been a dead end for a lot of amateur careers. When you get on phone, the time for code practice or working it

never comes again. Larry was in the trap, so was I. So if nothing else our level of tolerance is not as great as some but we know every self-deception in the book. As Billy Sunday once said of Satan, "I know there is a Devil because the Bible tells me so and because I have done business with the bastard personally". I won't lead a man there any more than I would lead him to an open door to unlit basement steps.

At least prior to 1991 the Tech, at least in theory, had to pass 5 wpm so he had some idea of what it was he was evading. Since then, we have developed Lifer Tech Syndrome, Dick's bugbear. Characteristics of this syndrome, a big campaign dedicated toward deceiving both the world and oneself, include:

a. Joining NCI and playing like the code requirement was even a debatable issue within a five-year horizon. Never miss the opportunity to say or write 'Morris Kode'. Note Leland's nearly-indecipherable tag line.

b. Joining everything, subscribing to everything, going to Dayton every year. Activity signifying not a hell of a lot.

c. Entering into every discussion on 'leading edge' technology. Nothing, of course, is ever done just talked about. Knowingly pronounce everything in existence as a 'legacy mode'. Become the resident genius on arcanity -- you too can be the guru of 160 meter gray line propagation.

d. Where anyone has actually achieved anything, even a simple-minded code test, he must be attacked, unhorsed, and mugged. Larry has built a whole new hobby on these dipsticks.

e. Whining endlessly about slights real or imagined. The object, of course, is to punish verbalization of what everyone in the vicinity already knows. In communities of the terminally incompetent the crushing line is "You think you are better than everyone else." When the response is, "I not only think it I know it" it is time for the riot squad. Equality is another word for nothing left to lose -- or more precisely never having gained it to begin with.

I do not play the game nor do I tolerate it.

Dick NBK

5311. HyTower

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-19 20:15:20 UTC
From: Mark Erbaugh <mark@nospam.microenh.com>
Message-ID: <3ab6698b$0$11820$f5f63664@news.tdin.com>
Source record: 168183

I've always been fascinated with the HyTower antenna. One of my father's (a non-ham) friend was a ham and he had one in his small lot. I thought it was the neatest antenna, especially when I was a 15 newly licensed novice and my dad wouldn't let me put up antennas.

Anyways, I notice that the HyTower is back in the MFJ / Hygain catalog and I am seriously considering one for the antenna farm at my new QTH. I realize that the entire tower is part of the antenna so mounting other antennas directly on it is probably not a good idea. However, is there a way to use it to support a wire antenna? I'm thinking about installing a Carolina Windom 160 and wonder if I can use the HyTower to support either one of the ends, using a length of rope to isolate the two antennas.

If anyone has a HyTower available, I'd be interested in price and condition.

My current plans for the antennas include:

The HyTower as a vertical antenna
The Carolina Windom as the horizontal antenna
My current Force 12 C4S beam for 40, 20, 15 and 10.

I'd use the Force 12 tower to support the center of the Windom.
Ideally, I'd like to use the HyTower to support one end of the Windom and a mast of some sort for the other end. There are no trees at the new QTH and the Radio Works website cautions about installing the Windom's as inverted vees.

Mark, N8ME

Tom, W8JI wrote:
"If you short the electric field, you are shorting the desired signal as well. They are inseparable."

Terman says they are separable. I`ve already provided his direct quotations. Tom may not agree.

I`ve worked at several broadcast stations. All coupled to their radiators inductively, using a Faraday shield between the cols. It is standard practice as capacitive coupling between the coils acts as a high-pass filter enhancing harmonic feed to the antenna. That shield not only suppresses the harmonics but it serves as a major lightning defense. These shields have the pock marks to prove they work.

I`ll add B. Whitfield Griffith Jr,`s remarks on the topic:
"The process of radiation is not the only means by which energy can be transferred from one circuit to another; if the magnetic lines of force which arise from the flow of current in one circuit happen to pass around, or link, the conductors of another circuit, then there is a mutual inductance between the two circuits,"-----"It is often desirable and practical to allow one type of coupling between two circuits and to eliminate the other. Fig 28-1, for instance, shows two coils which are coupled but have a special type of shielding between them that causes the coupling to be purely inductive and not capacitive. This consists of an array of parallel wires which are grounded at one end only. The lines of electric force from the coils terminate on these grounded wires, so that there are no electric lines of force passing directly from one coil to the other and hence no capacitive coupling. On the other hand, since the wires do not form closed loops, there is no circulating current in the shield and therefore nothing to stop the penetration of the shield by the magnetic field. This type of shield has long been known as a Faraday screen.

The book is "Radio-Electronic Transmission Fundamentals". Don`t know how the separation of magnetic and capacitive coupling could be explained more completely and simply.

Best regards, Richard Harrison, KB5WZI

Hi All,

Again, the corruption of language reveals itself in contradictions WITHIN the discipline that does not fully qualify its own definitions.
- sigh -

And Richard, you are right as far as you go, but the dispersion is an artifact of differences in Zo; not in their being resistive or reactive (although this is a basic consideration).

It simply relates to the metaphor of the prism in that the interface between two Zo's (or in optics, the indices of refraction) cause the applied signal to differentiate along wavelength such that the interface deconstructs the signal into slower and faster data arriving out of phase/time with respect to their original orientation. Or in terms of this metaphor, a white signal is translated into the spectrum of its constituent, colored components. Some of those components travel a greater distance than others and special care must be taken to reconstruct such a signal to recover the data without distortion.

The optical solution to this is found in the use of a transmission line with variable density, where the variation is found radially out from the coaxial center (this would be a blast to see in transmission lines, but I'm not going to hold my breath for an example).

This variability is added to the design to pull the spectrum of constituents together and keep them that way. Another design variation is call mono-mode and relates in similar fashion.

Thus the balkanization of terms with the imprimatur of being a standard expression within a technical community reveals itself for what it is, committee generated jargon with less than particular care for prior usage. When someone expresses the fact that something dissipated an applied signal, I needn't challenge them for a specification for temperature rise, and I certainly wouldn't challenge them with the observation that this heat must have in turn dissipated from its load to the environment. This is, as pointed out by both sides, the commonplace expression and expectation. However, those arguing this specious meaning of dissipationlessness would take the trouble to argue that the heat does NOT dissipate (which would confound their rigid logic) and turn their backs on centuries of established understanding within science and engineering. Even though the terms are understood and used in these common ways, this is not a rigorous basis for a formal definition, but rather for a dictionary of argot and cant (which is all that the IEEE can aspire to be in all reality).

And the question remains: "So What?"

Because even though the balun won't work correctly, at least you'll be
doing what they tell you.

Now picture this Peter. These people that manufacture the antenna (if
it is the same one I had experience with) obviously don't have a clue
how a balun works.

Scary, isn't it?

>NOT a loop; it is open at the center.

The shield IS the antenna. Get a copy of a later Reference Data for
Radio Engineers, and read it.

The shield IS resonant (if the center conductor is tuned to resonance)
because the mutal coupling between the shield and center conductor is
virtually perfect.

Sometimes we will ignore all plainly evident facts to make an antenna
have magical properties.

1.) The time-varying fields can NOT pass through a conductor several
skin depths thick. They get to the inside of the loop by "spilling
over" the cut in the shield. If you measure voltage across the gap in
the shield, that voltage will equal the voltage of a single turn
inside the loop.

2.) If you short a turn (or turns) inside the loop, the voltage across
the gap in the shield goes to zero (except for a tiny voltage
remaining from losses).

3.) If you short the gap, you force the voltage to zero and the loop
goes dead.

4.) We know fields don't penetrate coaxial cables, and accept the fact
the current must "spill over" at the ends to create common mode
current outside the cable. We can't measure either MAGNETIC or
ELECTRIC fields outside the cable to any extent unless we allow this
to happen, no matter what shape we form the coax into. Yet a few of us
blindly insist it can happen in a loop made from coax!

5.) Even if we could violate every rule known and have fields pass
through the shield, the effect on noise would be ZERO. Noise is a

signal, just like any other signal.

6.) About 1/10th of a wavelength beyond the small loop antenna, the field impedance INVERTS. What was a strong magnetic field and weaker electric field NOW becomes the opposite. So much for the bologna that magnetic antennas are "quieter" because they are "magnetic".

Not only does shielding NOT happen, even if it did happen it would make no predictable difference in signal-to-noise ratio.

All the shield does is allow us to balance the antenna. There are a dozen ways to accomplish the same thing without a shield, and it is just as eas to screw-up the antenna by adding a "shield" if it is done incorrectly.

Faraday shields, for RF applications, are strictly common-mode devices. Thay have absolutely NOTHING to do with stopping electric fields from interacting with the antenna, and normal coupling of electric fields in a transformer.

If the system is built right, they are totally unnecessary. If the shield is grounded or constructed incorrectly, the shield can make things worse.

Whenever I hear someone bad mouth CW as you are it is either because:

a.) The person is too lazy to learn it or
b.) They have overly bright pink skin, wear lipstick and go by "Monique".

CW happens to be enjoyable for many (certainly not all) hams and it still has a 14dB advantage over SSB which help those who live in a CCR&R area where large antennas are not possible. Look at all the QRP rigs being sold. I think there are just a few too many crybabies who don't wish or know how to work towards a goal and would much rather complain.

Just my $.02

When I got into ham radio in 1987 I took a step that was a big one for me. I have learning disabilities. Math; never got past 7th grade. Retention meant repetition until I "got" it. I learned by watching, and mimicking what I needed to learn. Typing took a long time but I learned it. For years I faked a lot of stuff. I very good at anticipating what the instructor wanted from me and could give the answers out-. But to sit down and take a test was gosh-awful. I failed the code portion of my Novice ticket. But a VE saw what was going on with me and he gave me the test again in another room. The Tech class took two testing sessions, so did the General, again the code. The Advanced test took three trips in years time and the Extra took two times. My "ELEMERS" taught me how to do the formulas that would be on the test and that was a chore believe me.

Why, you ask, am I "confessing"? Well following this string has revealed something that I picked up on in 1987. Amateur Radio is, to some individuals, "THEIR" hobby, and if you do not meet or exceed their station in the hobby then you do not belong on the same level as they do. These folks have no bones in telling you that you do not belong either. I hid my "learning disabilities" because I was ashamed of it. I missed out on a life time of adventure and excitement in during the 50's, 60's, 70's, and half the 80's because of that attitude. You would have to live it to know what I am talking about.

When I see someone say something about knowing code or you are not a "real" ham makes me want to throw up. A true ham radio operator is one who knows what the word "ELMER" means and puts it into practice. Packet is part of ham radio. But I do not practice it, nor slow scan TV, or satellites. But I do love SSB and CW. Am I a ham? You bet. Is the person who takes the tests, one at a time a ham? You bet. And shame on you who says it ain't so!

I know many hams who got in ham radio on the no-code ticket. Guess what? Most of them go after the code with a vengeance. Why? Because someone took the time to show how much fun it is. If the person who is a VE does not want to work with the Tech tests, get out. Stay out. Sell your ham gear because you are hurting the hobby more than you will ever know!

I love the Morse Code. I now send and receive about 17 words a minute. Any faster and I lose it. If someone does not want to reply to my CQ because it is too slow for them, well, that is their loss. I am sure the hams that loved "spark-gap" era felt the same way about the "modern" advances that did away with "sparky" as a lot of hams feel about the Morse Code. But change is part of life. Hell I would love to be stuck between 1950 and 1960. Those were the best times of my life. My mom and dad were my best friends, my brothers and sisters were also. Everything was in place back then. No real worries. Not a whole bunch of cruel people around then either. But folks

time moves on. Most of us adjusted and changed with the changes.

The amateur radio hobby will be here for a long time, if change is accepted, and everyone quits trying protect "their" area. You who love the code as I do will see to it that the "code freqs" will be protected. I can not imagine not being able to use code on the bands.

We will lose our precious and valuable airwaves if attitudes do not change. Motorola is just waiting for that not to happen.

Beg to differ on this one. The field does not reach the inside by a current "spilling over the edge" and
back along the inside surface. This "loop-current-over-the-open end" fallacy has been floating around for
quite a few years.

It is also not true that an EM wave cannot be transmitted *through* a Faraday shield. It happens all the
time.

Skin effect does not operate to prevent this coupling from the outside to the inside. At any particular
location on the shield, there is no skin effect between the outside and the inside, measured directly
through (perpendicular to the surface) the thickness of the shield, which is an excellent conductor.
Skin effect doesn't work like that, it only works for a current that is flowing along the surface, not
directly through the thickness. Also, a net current does not flow along the length of the outer surface
for the simple reason that it is open-circuited, just like any other conventional transformer, which is
exactly what we are talking about here.

The induced EMF and charge distribution on the outer surface exists identically on the inner surface.
This EMF and charge distribution on the inner surface creates an EM wave at the inside of the shield that
then propagates to the turns of the inner multiturn loop. Depending on the load resistance connected to
this multiturn loop, a "counter-wave" can also be created that reflects back to (and through) the shield.

A length of coax shield that is not shorted to itself is an excellent Faraday shield and does not stop
the transmission of an EM wave. This wave is "re-created" in-phase at the inside of the shield. There is
no mickey mouse phase shift due to a travel time around the open end of the shield and back into the
inside of the shield. The wave inside the shield is exactly in-phase (or very damn near)

with the wave on
the outside of the shield.

In an open-circuited length of coax Faraday shield there is no circulating current. It is just like any
other open-circuit winding on any other ordinary transformer.

There is a simple and interesting way to see what is going on along the length of the Faraday shield.
Imagine that the shield is composed of a very large number of very small segments. Within each segment
there are two things 1) an induced EMF created by the incoming wave and 2) a charge distribution due to
electrons. These two fields cancel each other so that the "net composite" E field within that tiny
segment is zero, just as it's supposed to be. But because of the charges, each segment is like a small
open-circuited battery. The total voltage is the sum of these many individual voltages. And because the
net E field in each segment is zero, and because the shield is open-circuited, there is *no* net current
flow along the surface.

Now suppose the incoming EM wave suddenly reverses direction. Within each tiny segment the induced EMF
and the charge arrangement both quickly reverse directions. The zero net E field is maintained at each
and every location. This reversal occurs "locally" and there is no "sloshing" of electrons (current flow)
from one end of the shield to the other. The EMF and charge distribution are both *uniform* along the
length.

Is there any dissipation in the copper due to these reversals? Yes, there is a small dissipation within
each tiny segment due to the reorientations of electrons within that segment. In other words, an
open-circuit transformer winding will dissipate a very small power due to high frequency cycling within
each of the many tiny segments.

There is another interesting thing. Text books tell us that a wave cannot penetrate a good conducting
surface beyond a few skin effect depths. That would seem to refute what I have been saying here.
However, if we look more closely at the textbook, it specifies that the surface must have an
unrestricted current flow, in other words an infinitely large surface. The reason is that it is this
current flow that creates the opposition field that creates the reflection. The wave is not just bouncing
off of the surface like a golf ball against a stone wall. It is the surface current that creates the

reflection. That is why we see skin effect mentioned with regard to depth of penetration of the wave into
the surface.

A shield room that is buttoned up tight also approximates just such a surface so that surface current has
an unrestricted continuous closed path. That is the basic principle of the shield room and any other RF
magnetic shield (Terman 1955). The basic principle of the Faraday shield is that a continuous or closed
path for current does not exist, therefore an EM wave can pass through with very little attenuation in
the manner that I have described. A very thick shield material could create some problems, but a single
coax braid is OK at HF, at least.

I have a Rohn 45 foldover and Rohn Dwg # D770022 R5 specifies four
guys with the anchors 18' from the base of the tower. This is
assuming that there are two 10' full sections above and below the
hinge section. If there is an extra section in there someplace then
the distance increases to 25'.

The '45 hinge section has welded tabs for guy attachment, so it is
obvious where they connect. I can't speak to the '25 tho...

I've been lurking in this group for some time, and I can tell you H.A.M. operators have some very mean-spirited and retrograde attitudes, but this is the worst example of them all. Ever since Cowboy Bush stole the election the right-wingers and animal-haters have been licking their chops. Well, I draw the line HERE. I think what needs to happen now is for Mr Aycock to post an apology in this chatroom with a pledge not to commit such acts again. I've already made note of the laser antenna and it's potential dangers to wildlife. Needless to say, I'll be campaigning for an outright ban on this device.

Richard Clark wrote:
"---you are right as far as you go--"

If I were half the mathematician that Oliver Heaviside was, I`d have completed the exercise. I thought I was doing well just to remember Heaviside`s criteria for over 50 years. (R/L=G/C)

If a line is going to treat all frequencies the same, it must look like a pure resistance. This was especially important to telephone companies. Heaviside realized this and invented the loading coil.

Heaviside invented vectors and that may be his biggest accomplishment, although he made J.C. Maxwell`s equations understandable and useful to ordinary engineers. Heaviside was born in 1850. He was mostly self-taught as a London mathematician and scientist. Oh yes, he also got at least part of the credit for describing ionospheric reflection and got the honor of having the reflecting layers named for him, but while I think Hertz should go away and we should go bact to CPS, I see nothing wrong with a Heaviside layer. But alas, the use of Heaviside`s name has faded while the name of Hertz has not.

Best regards, Richard Harrison, KB5WZI

What a bunch of bullcrap, Dick. I don't know of a single person that wants to "have it all on the strength of his codefree tech written test." Instead, what most of us (Techs) want is to be able to use the capabilities that the FCC has authorized, without constantly being harrassed for using those capabilities differently then you might use them (in other words, stop endlessly judging us).

In addition, like all human beings, we would not mind a little respect - not as a ham operator (I know we'll never get that from you, no matter what we do), but simply as a human being who wants to enjoy life without all the endless insults (the crap you wrote above or the "no-code equals no ham" nonsense, for examples).

And finally, some (not all - some don't mind the code tests and some have no desire to upgrade at all) want an opportunity to upgrade without spending weeks learning an absolutely antiquated communications mode that very few, if any, outside of ham radio uses anymore. By the way, describing code as an "antiquated communications mode" is not a judgement, a put-down of code users, or even an opinion - it is a fact.

Now, every single person that I've met who feels that way is more than willing to meet reasonable requirements (the written tests, for example), so it is not an situation of wanting something for free. Instead, they all seem to be saying they want a fair price for what is offered (and learning Morse Code is not a fair price simply because you once had to pay it).

Once a noted wealthy ham went on a safari to Africa and came
home with a monkey. He brought the monkey to a club meeting,
and cornered the ham class guru. "I'll give you a hundred
bucks to get my monkey ready to take the Tech test". The guru
demurred. "Five hundred bucks." More denial. "A thousand
bucks." Finally the guru said "OK, but it will take 18 months."
"Deal" said the ham with the monkey and departed.

"Hey, old buddy, what kind of a deal is that?" said the guru's
pal. "Look", the guru said "in 18 months anything can happen.
The ham can die. The monkey can die. And even if not, you
ought to see some of those folks that I have to prepare....."

Dennis:

There seems to be some confusion as to the terms and processes we are discussing here. Consider the total energy delivered to the antenna. First, if the antenna is lossy, some portion of the energy delivered to the antenna will be "dissipated" in or at the antenna. Dissipation infers loss, in that the dissipated energy is lost and not available for radiation. "Radiation" is the process through which the antenna converts the energy delivered to its terminals into a traveling EM wave in space. This process is "radiation", it is not "dissipation" nor is it "dispersion".

The "dispersion" process that we have been discussing is what happens to the EM energy after leaves the antenna. Is it "dissipated" in space or is it "dispersed" in space? Again, dissipation of the traveling energy infers a much different process than dispersion of the traveling energy. Dispersion in itself may be a poor choice of a word. "Spreading of Energy" may be a more appropriate term.

I think you're confusing processes again. The energy converted to heat
would be dissipation. The energy radiated would be radiation. Again, we
are discussing the concepts of what happens to the radiated wave as it
travels away from its source.

I am not sure what part of this you don't see as true. Perhaps you could
explain.

Consider this:

The antenna is an isotropic source with 0 dBi gain. Why is the EM field
density different at a distance of 10,000 km as compared to the EM field
density at a distance of 1,000 km?

After answering that question, consider this: At any distance from the
antenna, if you were to integrate the energy density or energy intensity
over a sphere surrounding the antenna, the total energy over the sphere
would be the same. The total energy does not decrease with distance, it is
not "lost" nor does it decrease as it travels. This is why the radiated
energy is not said to be dissipated as it travels - it is dispersed (spread
out or thinned) in space. The term dissipation would infer the loss of
energy, which is a different process than the spreading out of the energy.
There is no energy lost as the wave travels (considering the total sphere
surrounding the antenna). The fact that we do not have a mechanism to
capture all of this energy is another separate issue.

One of the most confusing definitions is that of free space path loss. It
is written as a function of distance and wavelength (frequency). As a
result, many assume that there is more "loss" of traveling energy with
increasing frequency as if it were "dissipated" somehow. Actually, the
process is the same for all frequencies. The frequency dependence is
introduced to account for the fact that the effective aperture of an antenna

is a function of frequency.

Defining dissipation in this manner seems to be a personal preference. If
you choose to define dissipation in this manner that's fine but it does not
sufficiently explain the process that an EM wave undergoes as it travels.

Hi Bill,

We have to be careful or we will perpetuate the myth that "magnetic" signals in a shielded loop pass right through the shield, while "electric" signals are shorted. That isn't true at all, and is easy to prove.

The "shield" does not change the field impedance of the loop at all. It does not sort the "magnetic" part of an EM wave from the "electric" part of an EM wave.

It does not sort signals from noise.

All it does is modify the balance of the structure, and improve balance if it is installed correctly.

5353. Installing a Cushcraft R7 Vertical - Advice

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-20 11:50:21 UTC
From: Don <k4wva@home.com>
Message-ID: <1uHt6.333613$j6.46978370@news1.rdc1.va.home.com>
Source record: 168025

I recently acquired a Cushcraft R7 vertical antenna and was considering a "near the ground" installation. This is one of the verticals which does not require separate radials since it has build in counterpoise rods at the base. The instructions indicate that "dangerouly high voltages" can be present on the counterpoise rods, and recommends a mounting height of at least 8 feet.

I will probably not run more than 100 watts through the antenna. Any one have experience with the this vertical (or similar) and the voltages that might be present on the antenna / counterpoise rods? Needless to say, after reading the instructions, I have to rethink the installation.

Any help / comments are appreciated.

From: Jim Rodenkirch <rodenkir@spawar.navy.mil>
Message-ID: <99dc7r$ao4$1@newpoisson.nosc.mil>
Source record: 167865

O.K. Dave: I've got Bill Orr's book, "Vertical Antennas" in front of me. The authors are William Orr, W6SAI and Stuart Cowan, W2LX. The book was published as late as 1993 by Radio Amateur Callbook (an imprint of Watson-Guptill Publications). Its ISBN is 0-8230-8710-7.

A great book for anyone getting started in verticals; e.g., separate chapters on radio ground/radials, Marconi antennas, antenna matching devices, ground planes, phased vertgical arrays, multiband vertical antennas, etc.

In the multiband chapter they do walk you through a multiband vertical for 80 through 15 meters. The vertical element is 20' (sorry, Ray - couldn't quite meet the requirements set by Dave that it be 16' so it would match the Gotham) and the coil is 35 turns, 2.5" diameter, 6 turns per inch (I seem to remember the coil supplied by Gotham as being similar in size). They do talk about approximating the coil tap(s) depending on the band and then using an SWR meter to select the final tap and thus minimize the SWR - yup, that's the way one usally does that. They show a radio ground symbol but do not spell out what that would be comprised of - that's discussed in the radio ground chapter. I would not drive an eight foot copper rod into the ground, connect it to the braided shield of your feedline coax and call it a day as you'll have very little efficiency. Figure on some sort of ground screen, radials, or whatever - just like they talk about in that chapter.

So, Dave - get that book or one like it (I believe an earlier post by AI6V mentions a couple of other books that might work for you) and you'll be wired for stereo.

An aside note: They spend some time on top loading as well which is my next step in my quest to extend my ground plane system. I've got the capacitive hat built but need the weather to cooperate some so I can install it and do some tuning and messing around to see if I can get my system to tune down to 80 meters.

Regards, Jim R.

"Jim Rodenkirch" <rodenkir@spawar.navy.mil> wrote in message news:994ut6$s18$1@newpoisson.nosc.mil...
And, Ray, Dave's mention of a "similar" antenna is what prompted my reply to him. The book that has that antenna is the Vertical antenna book written by W6SAI - believe his name was Bill Orr???

I've got it at home and had it sitting out to bring in today but - didn't; another example of CRS setting in! I'll have it here tomorrow to pass on to Dave as it has discussions on several antennas that are similar to that old Gotham thing.

That Gotham worked about as well as a wet noodle did. However, back then I was 12 to 14 years old and didn't know a radial from a radio - or something like that. My exposure to antenna theory and construction was extremely limited, as opposed to today where it's merely limited - LOL!

Yep, all dem radials and the tuning done at the antennas base make all the difference in the world.

For Dave: I'll have that book info tomorrow A.M. Regards, Jim R.

"R. Makul K1XV" <k1xv@arrl.net> wrote in message news:06e5bto2hekhdtajdkp8gip6uh3o5c05bq@4ax.com...
Jim: I did read it. Dave's primary goal is to build a REPLICA of a Gotham Vertical based on its original specifications, or plans for a SIMILAR antenna.
Jim, to me, a replica to a Gotham Vertical means one that is a simple multisection thin wall aluminum tube end fed through a B&W inductor at the bottom, attached to the hot side of an unbalanced antenna coax via an alligator clip so you can vary the inductance by changing the tap location on the coil with the alligator clip. The ground side of the coax attached to a ground rod. The whole thing then attached to the side of a house or to a non conducting support via "u" straps.

I agree. The entire electromagnetic signal goes through the Faraday shield, no sweat. But it does it vicariously. The EM signal is "re-created" on the inside. This is important to understand.

Ideally, the Faraday shield is "transparent", but it would be tough to claim that there are no small insidious shenanigans going on. Nothing is perfectly wonderful.

> The "shield" does not change the field impedance of the loop at all.
> It does not sort the "magnetic" part of an EM wave from the "electric"

I agree.

> It does not sort signals from noise.

I agree, unless there is *direct* capacitive coupling to a nearby noise generator.

> All it does is modify the balance of the structure, and improve
> balance if it is installed correctly.

I agree. The Faraday shield acts as a "barrier" for direct capacitive coupling, what is called "electrostatic" coupling. The electrostatic capacitance is the DC capacitance, which is the same as the RF capacitance of a pure physical capacitor (no L or R).

Dear Al,

The Loop is only available from me.

The price of the ALA 1530 is GBP 140 including shipping.

Please send International Money order (from Post Office) or a Sterling
bank Draft.

Credit card transaction; just send your full name, address and Card no
and expiry date to the Shortwave Shop in Christchurch. E-mail
sales@shortwave.co.uk or you can fax details +44 1202
490099

Delivery is about 20 days from receipt of order.

Kind Regards

One other thing. The Faraday shield does introduce some capacitance from the inside loop turns to ground. The tuning circuit should take this into account. The spacing between shield and coil should be not too close. The effect of the shield on the inductance of the coil is quite small, but maybe not exactly zero.

I have three Yaesu FT50RD hand held transmitters.

One is a 7 . Buy it for $160.oo.

#Two is a 7. Buy it for $160.oo

#Three is a 9. Buy it for 170.oo
All three units have original box and green serial number certificate.
The prices include shipping, handling, and insurance.
Reason for selling: Retired and Tooooo many handhelds.
They won't last long at these prices.
Guaranteed to not be D.O.A.

Cecil:

That's a good question. Maybe its just one form of "heat" in the first place. Maybe our skin acts as a heat antenna. I wonder what the heat gain is in that case?

My point has been that "dissipation", IMO, infers a process where the EM energy is lost through a conversion process, like the creation of heat. We cannot recover this EM energy because it has undergone a "conversion" (probably using the wrong word here too) process.

I would agree, that since we can't capture all of the radiated energy, it is essentially "lost". However, the fact that it is "lost" in this case is a result of our inability to capture it. It is not lost because it has been converted to another form of energy. It still travels away from the antenna as an EM wave. That's why I think dissipation is an incorrect term to use in this case.

Enough said from my end, I will let my opinions dissipate ....

What he's been doing isn't nearly as mean as waiting for a bird to fly through
and then turning the antenna on.

Such radiation would be absorbed or reflected or would pass through. Infrared heats the skin if it's absorbed. Of course, if the skin is in radiative balance with the environment it will emit as much infrared as it absorbs. It usually wouldn't be reflected unless you're aluminum. Other light waves, on striking the skin, would be converted into heat too, although some of the light is reflected. Some radio waves would pass through, as might cosmic rays and part of the x-rays. Of the radiation that is absorbed, I think there are two possibilities- that it ionises something, or that it's converted into heat.

If the shield is open circuited and the capacitance to the inner conductors is neglected, no circumferential currents will flow on the shield. If there is no current flowing on the shield, then the magnetic field will be as if the shield didn't exist and there would be no need for current "spilling over".

The EMF induced on the inner conductors is proportional to the time rate of change of the magnetic flux passing through the loop times the number of turns. This is true regardless of how the field is generated. Any current flowing on the inside conductors will produce a magnetic field independent of the existence of an open circuited shield. No requirement exists for either the electric or magnetic fields to 'flow through' the shield.

Based on my understanding of the scenario under discussion, an open circuted shield is transparant to the process of extracting energy from a magnetic field of the appropiate orientation as long as it is open circuited. The fields set up by current flowing on the inner conductor are the same as for any other common mode current.

> It is also not true that an EM wave cannot be transmitted *through* a Faraday shield. It happens all the
> time.

I suspect this statement is interpreted differently by the various participants of this forum. The existence of both a time varying electric and magnetic field are necessary for the existence of an electromagnetic wave. An electric field cannot exist inside a perfect conductor. Therefore, an E&M wave cannot pass through a perfectly conducting sheet of infinite extent. A Faraday shield has a strategically placed, nonconducting discontinuity, carefully located in a way to allow coupling between the two sides of the shield for some,

but not other time varying field configurations.

> Skin effect does not operate to prevent this coupling from the outside to the inside. At any particular
> location on the shield, there is no skin effect between the outside and the inside, measured directly
> through (perpendicular to the surface) the thickness of the shield, which is an excellent conductor.
> Skin effect doesn't work like that, it only works for a current that is flowing along the surface, not
> directly through the thickness.

Certainly no electric field can exist in any direction inside a perfect conductor. For this purpose, any real conductor more than several skin depths thick will behave as if it were a real conductor.

> Also, a net current does not flow along the length of the outer surface
> for the simple reason that it is open-circuited, just like any other conventional transformer, which is
> exactly what we are talking about here.

Agreed. As long as there is no current flowing on the outer surface, it has no effect upon the coupling between the inner conductors and the external magnetic field.

> The induced EMF and charge distribution on the outer surface exists identically on the inner surface.

The EMF induced across the gap in the outer surface will be nearly the same as that induced around the inner conductor (per turn), assuming the diameter of the loop is large compared to the radial distance between the outer surface and inner conductors. Charge distribution, and therefore electric field, depends critically on dimensions and is much harder to generalize in a few words, at least for me :-).

> This EMF and charge distribution on the inner surface creates an EM wave at the inside of the shield that then propagates to the turns of the inner multiturn loop.

I think the best way to look at a loop antenna which is small compared to a wavelength is to separately consider the effects of the electric and magnetic fields as they interact with the antenna structure. The size of the space between the shield and the inner conductors surely is much smaller than the dimensions necessary to support propagation of an electromagnetic wave.

> Depending on the load resistance connected to
> this multiturn loop, a "counter-wave" can also be created that reflects back to (and through) the shield.

Current in the inner conductors will create a magnetic field which is substantially the same with, or without the Faraday shield. The fields are predominantly reactive in the immediate vicinity of the loop structure and do not generally posses the characteristics of a

propagating electromagnetic wave. Unlike the electric machinery
profession where the concept of a 'flux wave' is illustrative and
commonly used, in the context of antenna theory, 'wave' usually refers
to a propagating electromagnetic wave.

> A length of coax shield that is not shorted to itself is an excellent Faraday shield and
does not stop
> the transmission of an EM wave.

Agreed.

> This wave is "re-created" in-phase at the inside of the shield. There is
> no mickey mouse phase shift due to a travel time around the open end of the shield and
back into the
> inside of the shield. The wave inside the shield is exactly in-phase (or very damn near)
with the wave on
> the outside of the shield.

The shield simply has no significant effect on the electric or magnetic
fields associated with an electromagnetic wave propagating perpendicular
to the plane of the loop because there is no current flowing along the
shield. No current flowing means no charges moving and therefore no
secondary electric fields of significance except perhaps across the gap.

> In an open-circuited length of coax Faraday shield there is no circulating current. It is
just like any
> other open-circuit winding on any other ordinary transformer.

Yep, at least if the capacitance between the shield and inner conductors
is neglected as is appropriate while initially developing an
understanding of the fundamental physics.

Typical practice for wideband receiving loops is to terminate the inner
conductors directly into the input of a high impedance preamplifier.
Typical amateur practice is to conjugatly match the loop to the reciever
(or transmission line) by providing a resonating capacitor and matching
network. The effect of resonating the loop is to increase the voltage at
the loop terminals to many times the voltage induced by the external
magnetic field alone. This increased voltage is due to the secondary
magnetic field generated by the circulating currents in the tuned
circuit.

In this resonant case, the capacitance between the outer shield and
inner conductors can be the majority of the tuning capacitance and
carries the circulating current associated with the resonant circuit.

> There is a simple and interesting way to see what is going on along the length of the

> and every location. This reversal occurs "locally" and there is no "sloshing" of electrons (current flow)
> from one end of the shield to the other. The EMF and charge distribution are both *uniform* along the
> length.

The EMF induced by a time varying magnetic field is only defined around
a closed path. As you say, the electric field inside the conductor is
zero, therefore the potential difference (EMF), which is defined as the
integral of the electric field, between two points on the same
conductor, is zero according to classical electromagnetics.

> Is there any dissipation in the copper due to these reversals? Yes, there is a small dissipation within
> each tiny segment due to the reorientations of electrons within that segment.

An electric field does exist external to the conductor. This electric
field causes a redistribution of charge on the surface of the conductor
(in the time varying case) which can be thought of as charging the
capacitance of the dielectric surrounding the conductor. Usually this
capacitance is considered parasitic and steps are taken to minimize it
and the associated conduction currents.

> In other words, an
> open-circuit transformer winding will dissipate a very small power due to high frequency cycling within
> each of the many tiny segments.

In my circles, it's considered to be I^2 * R loss associated with the
current required to charge the interwinding capacitance.

> There is another interesting thing. Text books tell us that a wave cannot penetrate a good conducting

> the surface.

The infinite conducting sheet is a fairly easy scenario to attack analytically as are certain closed volumes. In general, you must properly pose the entire problem, express it as a set of partial differential equations with appropriate boundary conditions, and then attempt to solve the entire system. However, I think it is completely rigorous to state that a wave cannot penetrate a good conducting surface beyond a few skin depths.

> A shield room that is buttoned up tight also approximates just such a surface so that surface current has
> an unrestricted continuous closed path.

Agreed.

I'll be off-line for a few days.

The voltages at the ends of radials while using 100 watts can run into
several hundred volts.

So how many Hams operate 20' dishes?
Where can I see details of the fabrication and operation of such beasties.

If they are home made how do Hams get a good figure.

I do know one method for getting a superb parabola , and the technique would
be readily available to any ham willing to move a lot of earth and bricks
around.
Though perhaps a one off could be done with just an earth mould.
I have seen 40' commercial dishes made by this technique with excellent
figure and very stable and capable of being knocked about by the military.
I'm sure that a Ham could build one, the question is has anyone?

Frequency of Operation fo -|- 4.34E+08Hz -|-
Wavelength of Operation l -|- 0.69m -|-
Dish Diameter -|- 6.00m -|- 19.68ft
Dish height h -|- 10.00ft -|- 3.05m
Dish Radius r -|- 3.00m -|-
Dish Area A -|- = p r2 -|- 28.274m2
Dish Gain Ga -|- = 10 log10 4pA / l2 -|- 28.7dB
Beamwidth -|- = 2 tan-1(2 / 10^(Ga / 20) -|- 8°
23'
Half
-|- 4° 12'
Fraunhofer distance -|- = 2D2/l -|- 104m

To squeeze the extra dB to take you to a gain of 30 dB needs a dish nearly 7 m diameter, now that is beginning to get a bit of a problem.

Going up to 1296 gives a gain of 38 dB and a beam width of 2° 49'
which is beginning to become respectable. the method of fabricating a dish that I have in mind should easily produce a surface that will work well at the higher frequency.

Frequency of Operation fo -|- 1.30E+09Hz -|-
Wavelength of Operation l -|- 0.23m -|-
Dish Diameter -|- 6.00m -|- 19.68ft
Dish Gain Ga -|- = 10 log10 4pA / l2 -|- 38.2dB
Beamwidth -|- = 2 tan-1(2 / 10^(Ga / 20) -|- 2 49/60
Half beamwidth -|- -|- 1 24/60
Fraunhofer distance -|- = 2D2/l -|- 311m

Of course a real leap forward would be to go up to 13 cm; where the professionals work for this type of communication.
A dish gain of 44 dB and beamwidth 1° 31'
is beginning to approach the 0.5° apparent diameter of the Moon.

Frequency of Operation fo -|- 2.40E+09Hz -|-
Wavelength of Operation l -|- 0.13m -|-
Dish Diameter -|- 6.00m -|- 19.68ft
Dish Gain Ga -|- = 10 log10 4pA / l2 -|- 43.6dB
Beamwidth -|- = 2 tan-1(2 / 10^(Ga / 20) -|- 1 31/60
Half beamwidth -|- -|- 46/60
Fraunhofer distance -|- = 2D2/l -|- 576m

16 dB more gain and a much lower slot in the ionosphere with water attenuation still fairly low. This wavelength is the cross over point for optimum space communication.
Some care in making a Cassegrain Antenna will realise a noise improvement as the dish illumination over spill is now filled by the coolth of the sky instead of the warmth of the Earth.
The big problem seems to be windage and a structure strong enough to withstand the bad weather.
As only the Moon is to be tracked a fairly simple Equatorial Mount is possible. it will have only an Hour Angle drive motor and the Declination is set manually and lock off with a spanner. As low angle tracking with such a

small dish would pay quite a noise penalty from horizon noise the tracking mount can be further simplified by only needing to track between the 30 degree above horizon points the dish edge doesn't contact the ground so the dish can be mounted lower down, this will help the stiffness of the structure and make adjustment from the ground easier.

>Engineering Handbook".

You can quote out-of-context whoever you like, but it doesn't change the way the antenna behaves. Everyone here seems to agree that the shield does not change the response of the antenna to anything that would happen more than a few loop diameters away, and I'm sure the "experts" you quote would agree also.

It is easy to confuse common-mode coupling problems, which are related to balance of the system, with response to noise or signals more than a loop diameter or two away. Unfortunately easy isn't always right.

The shield does absolutely nothing to sort the electric field from the magnetic field, all it can do is change system balance. There are a dozen other ways to accomplish the same thing.

You shield the loop, you don't shield it, and it responds to time-varying fields exactly the same way. The field impedance is exactly the same.

If you add a "shield", and ground it improperly (such as off the electrical center) the response to unwanted fields can actually increase. That is because it unbalances the system. Many articles incorrectly show this.

Enough of defending the old wive's tales. Let them die.

>to heat when it hits our skins or other objects?

Light will also heat your skin, as can be determined by going outside on a sunny day. The bulk of the radiation from the sun is at shorter wavelengths than infrared, and the carbon dioxide in the atmosphere blocks much of the lesser amount of direct infrared radiation we might receive, yet sitting in the sun still warms you. Much longer wavelength EM radiation, for example that present inside your microwave oven, will also heat you up, it just won't stop at the skin.

Light is EM radiation at the wavelengths predominately emitted by objects which are the temperature of the Sun. Infrared is EM radiation at the wavelengths predominately emitted by objects which are the temperature of our planet. As this represents the bulk of the naturally occuring EM radiation where we live it is unsurprising that we have both sense organs that are sensitive to these wavelengths and skin that is fairly opague (i.e. absorbing) at these wavelengths to allow us to moderate our internal temperatures.

That we associate "heat" with infrared wavelength EM radiation is really an accident of the temperature of our environment. If we lived in a colder place, "heat" would be associated with a longer wavelength of EM radiation. If we lived in a very cold place then heat would be RF.

Definitely do not agree. The inner surface of the shield "re-creates" an exact copy of the incident wave that continues on to the wires. The coupling to the wires is by electromagnetic wave propagation, whether the distance is 1/4 inch or 1/4 yard. To be more precise, the charge distribution on the inner surface begets an E field beyond the surface which is parallel to the surface (same as along the outer surface). But induced EMFs exist only within the shield. This isolated E field begets an orthogonal H field which encircles the center wire, which then begets a Poynting vector that is directed toward the center wire. This interpretation passes every test that I can think of. I am certain it is right.

This is not correctly stated. For a path in the *open-circuited conductor* the induced EMFs are balanced by electric charges at each location. This is the *only* reason why the net E field in the conductor is zero. Take away the charges (free electrons) and the E field is *not* zero, period. Across the open gap the voltage measured is not due (directly) to EMFs, it is due to charges. This is the only thing that my voltmeter knows anything about. We have had this discussion before, and I have considered this matter carefully. I am sure that I and my high quality literature references are right, and I am not going to yield one inch on this matter. The charges are important players and cannot be ignored. The reason why the net E field is zero in the conductor portion is exactly as I have described it.

This discussion regarding Faraday shields, wave reflections, depth of penetration and shield rooms etc is correct. Most of my discussion here on the internet is basically a repetition, with some additional insights since 1997, of my QEX article plus Letter that I sent you. My conviction is that there are no errors.

Ummmm..... gee looks like the people working at Tripod are human
after all and make mistakes just like you and me. At least they were men
enough to apologize and make things right. Whar's your beef or do you just
like to whine and moan.

In 'Transmission Lines for Communications' by C W Davidson (ISBN 0 333
37238 1) there is a proof of the skin effect which - far from requiring
an infinite surface - demonstrates that the effect will take place on
any arbitrarily *small* surface across which RF current is flowing.

No special circuit topology is required - the analysis seems to say that
if the RF current is flowing, for any reason, then there will be a skin
effect.

Bill has a copy of those pages which I snail-mailed a year or two ago.
If you still have it, Bill, please could you comment on its validity?

It was the best they could do at the time. As a satellite communications
book it is very good (or was for its time) because that is where the
author's undoubted expertise was. I feel it was a mistake to have over-
extended it to include moonbounce, on which it is very weak.

>> A 4m diameter dish for 70cm is a toy. It isn't big enough (in

>So how many Hams operate 20' dishes?

Or even larger? Probably well over a hundred, all around the world (I
don't propose to search the entire moonbounce address/equipment list to
check how many are 20ft or larger, because the total number of "dish"
entries past and present is 463!)

>Where can I see details of the fabrication and operation of such beasties.
>
Go to any search engine and just look for "moonbounce"... Google.com
just found 3640 pages!

>If they are home made how do Hams get a good figure.
>
If you mean surface accuracy, most people use ribbed mesh dishes up to
2.3GHz - and the majority of large dishes of this construction are
indeed home-made. The surface accuracy is achieved with a combination of
care in design, and patience in wiring the mesh (usually half-inch
chicken wire) on to the ribs.

>
40ft solid dishes are beyond amateur construction - not so much the dish
as the support and foundations required to hold it up, steer it
accurately and keep it up - but there are several amateur 40ft mesh
dishes.

[...]

>Some care in making a Cassegrain Antenna will realise a noise improvement as
>the dish illumination over spill is now filled by the coolth of the sky
>instead of the warmth of the Earth.

Cassegrain feeds are not practical below about 10GHz, for dishes of
amateur size, because the subreflector tends to cause too much blockage.
It tends to be more practical to use a conventional prime-focus feed,
which also allows easier band changing. Also the design of prime-focus
feedhorns has advanced considerably in the past decade or so, and
therefore spillover is less of a problem.

Forgive my saying this, but it is unnecessary to theorize as if it had
never been done. There are something like 30 years of intensive real-
world experience around - and the distillation of it is now on the web.

I don't think so.

> but I meant it then and mean it now.

I have no doubt about that Richard. Fortunately there are few like you out there. How I, or any no code Tech, chooses to follow their interests in Ham Radio is up to us. We don't have to meet your personal list of "approved activities" to be considered "real" Ham Radio operators. If that does not sit well with your vision of things, too bad, cry in your coffee, and move on.

License class advancement is not the sole goal in Ham Radio just as it is not in other areas of life either. Not everyone wants, or needs, to reach the Extra Class level the same way as not everyone needs to get a Ph.D. in their chosen field.

You strike me as the type of Ham who feels one is not worthy of being called a Ham UNLESS one follows in the foot steps you seem to feel is the only path to that title. You also seem to be unwilling to let others follow their own course, their own interests, and make their own choices in Ham Radio. Your vision of the path to being a "real Ham" is not the only one, nor is it necessarily even a good one. So you attempt to do what little you can to impede to process by refusing to help, instead you elected to hinder the process by shifting the burden to others. Seems a pathetic attitude where if you can't have it your way, you just wash you hands of the whole thing, such as being a VE, when it has anything to do with no code Techs.

As far as my tag line goes, if you can't understand it, try harder. I know plenty of other Hams, and non Hams too, who know exactly what I'm talking about. I will give you a hint however, it's a tongue-in-cheek joke about CW. If you can't figure it out after that, then your a lost cause.

Hi you antenna experts, here's a "tough one".

I am about to install a new tower, a 72 foot crankup, and I have two antennas: a Mosley TA33 with 40 meter add-on (in known good working order) and a Cushcraft A3S with 40 meter add-on (in good cosmetic condition, untested).

I'm only going to put up ONE of them. Which one would YOU choose (please choose from the two available antennas...thanks).

All input is gratefully received.

Neil, K1VY
K1VY@arrl.net

P.S. In order to test the A3S on the ground, what's the proper procedure. I've heard there are potential trap problems...

Hi back,

a two element phased array is not really that strange. you can do it many ways. The most practical method are two driven elements, seperated by .2 wavelenghts (similar to a 2 element beam/yagi) and fed with a special coax harness.

If you feed a tee in the antenna center, then have each leg go to it's respective antenna (but one leg has a 1/4 wave longer coax path...) you end up with a nice cardioid pattern which can be reference as an addcock antenna. A great direction finding antenna.

If you spit the feed near the center and feed with equal lenghts of 75 ohm coax from the tee, you get a colinear pattern. This is very similar to the pattern truckers get with cb antennas on each mirror of their truck tractor.

One does not have to use a gamma match, it just happens to be an easy method to match and feed an antenna. You can use a balun, end feed, hairpin, delta or loop. All my quarter wave antennas use a simple beta match. Nothing is in concrete...

cheers

What I'm looking for is a little more specific: I'm trying to find something in a directional 2m that would be suitable for mag-mounting on my car roof. (doesn't have to be remotely rotatable or terribly stable, I just want it to stand on its own while I'm sitting in a parking lot) I'd prefer something that can lay flat in the car while not in use, or could be rotated and folded down below the side rails of the roof rack (about 4" high) and bungeed down for short movements.

I'd also like a good directional antenna for SWL that could be set up while the car is stationary, but that can come later.

OBTW, the 2m directional would be primarily for listening. I'll have a 'daily use' antenna by the time I get around to setting it up.

The assertion that since the EM energy radiated by an antenna is
conserved, then it is not dissipated. All energy is conserved, so
by this definition it is hard to see how any energy is dissipated.

That is why I can't see how dissipation can be defined the way you
do. That is why I prefer to rely on the more fundamental thermodynamic
definition, that while energy is always conserved it is dissipated
when it undergoes an irreversible transformation. This, I think, is
the conventional understanding of the phrase "converted to heat". While
the phrase is ambiguous without a precise definition of "heat", it
describes what we normally consider to be the classic irreversible
energy transformation.

>The antenna is an isotropic source with 0 dBi gain. Why is the EM field
>density different at a distance of 10,000 km as compared to the EM field
>density at a distance of 1,000 km?

I presume this antenna is in space so what we're measuring is
purely path loss. While I'm pondering that one, then, you might
consider this one. What happens if I replace the antenna with
a resistor? Where does the power, which I presume you now think
is being dissipated, go?

The answer is that the power is entirely radiated in an EM field,
whose spectrum depends on the temperature of the resistor. If you
have an appropriate detector you'll be able to measure its
field strength. The relationship between the energy density at
1,000 km and the energy density at 10,000 km will be identical
whether the radiator is a resistor or an antenna. If you build
a sphere around the resistor you'll be able to detect all the
energy radiated by the resistor, just like the antenna. The energy
propagates away from the radiator in either case, and is not lost
in either case. Energy is conserved in either case, and in its

entirety ends up propagating away from the source as EM radiation
in either case.

So, what is the difference between the resistor and the antenna
which makes one dissipative and one not? What is the distinction?
I can't see one. In either case the power causes the antenna or
resistor to radiate EM radiation, and the energy which is radiated
has undergone an irreversible transformation in that it is impossible
to ever get it all back into the state is was in before reaching the
antenna/resistor. In both cases it is "converted to heat". What
happens after it leaves the resistor/antenna really isn't interesting
because the dissipation happened at, or close to, the resistor/antenna.

>> Irreversible processes are dissipative processes. The decrease in
>> the radiated energy density, and the resulting reduction in thermal
>> energy which can be extracted from the field by individual molecules,
>> is "dissipation" whether the EM energy actually finds molecules to
>> transfer the thermal energy to or not.
>
>Defining dissipation in this manner seems to be a personal preference. If
>you choose to define dissipation in this manner that's fine but it does not
>sufficiently explain the process that an EM wave undergoes as it travels.

Both the resistor and the antenna radiate EM waves. EM radiation
is a mechanism for heat transfer. What you are failing to address
is how you arrive at the apparent conclusion that EM radiation from
the resistor is dissipated while EM radiation from the antenna is not.

My definition may be a personal preference, but I prefer it because
it avoids having to resolve how the emission of some EM radiation could
be dissipative while the emission of other EM radiation is not. By
my definition they both are dissipation, and hence radiation
resistance is as dissipative as any other kind of resistance. You
have yet to resolve this dilemma using your definition.

5386. J-pole: how to avoid coupling to metal mast?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-20 22:35:12 UTC
From: Administrator <u127z@hotmail.com>
Message-ID: <MPG.1521f98ea6f514d0989680@news.customcpu.com>
Source record: 168063

How do I prevent a J-pole coupling (2 m band) to the metal mast? When I model the antenna, the metal mast strongly affects the VSWR and radiation pattern. The length of the mast heavily affects the antenna. I also find this effect on all vertical antennas I've modelled - GP's, 5/8 verticals, etc. Adding more ground plane rods does not seem to help. I expeced more ground radials to 'screen' the metal mast and reduce mast coupling. But it does not. Some antenna manufacturers claim their end fed vertical 1/2 wave antenna to be 'ground plane or metal mast independent'. Is this talking bullshit?

Is the only way to use a vertical dipole instead, mounted on the side of the metal mast as below, in order to avoid coupling? I understand the distance from the mast shall be chosen for minimum radiation pattern distorsion.

Gentlemen, perhaps I haven't made it clear that I am asking for advice
about an antenna problem and not a bicycling problem. I have in excess
of 80,000 miles on bikes, and the last 8 years on recumbent bikes (the
ones that look like lawn chairs on wheels). I consiider myself to be
experienced AND safety concious and do not feel that I need a flag to
be safe. My lack of accidents or even close calls seems to back me
up.

My primary concern is if the fact that I want to have an antenna
running very closely in the same plane with the support for the
fabric, am I going to have reflection or directional problems. I can
use a rubber duck, but the range is not what I want. So I will again
ask for advice.

You really want to get those 1/2 wave types as high as you can. They
will work quite a bit better than down low. They don't require ground
radials, but that doesn't mean the ground losses when mounted near the
ground are going to be low. They will be fairly high. Maybe not quite as
bad as a 1/4 wave with no radials though.
The short radials on the R7 are more used for a decoupling section,
rather than radials to reduce ground losses. For one thing, they would
need to be resonant to do this job on the elevated antenna. The radials
just minimise the currents on the shield of the coax so it doesn't
become part of the antenna. So in effect, it has NO radials used for
reducing ground losses. So you don't want it near ground level if you
want it to live up to it's potential. You might consider a radio shack
pushup mast. This would be perfect for one of these. They have a 19 ft
version which would do ok. If you went with the 36 ft mast, it would
perform very well. As far as the voltages, with a 100w radio, you are
probably looking at the 800-900 volt range at the high voltage points.
About the same as with a dipole at the ends I would think. The main
difference between these and the 1/4 wl ground planes, is the 1/2 wave
doesn't require the radial set to complete the antenna the way a 1/4
wave does.
Although lower, you still need to consider ground loss with the 1/2
wave. When I used to run a full size GP at 36 ft on 40m, a friend of
mine ran a R7 at about 15 or 20 ft. To VK land , his antenna did a
pretty credible job compared to my full size antenna. He was a tad

lower, but not a whole lot. MK

Steve,

How about this. Go out and buy the most sensitive set of infrared
goggles (i.e. a detector of infrared wavelength radiation) you can find.
Then, on a calm cool night, take a look at your antenna and feed line, as
well as the resistors and transistors or tubes in your transmitter,
when the latter is operating. The energy you say is lost is being
radiated as EM radiation, you can see some of it with the goggles.
The energy you say is not lost is also being radiated as EM radiation.
What is the difference? Are you defining "dissipated" as the radiation
you don't want, and "not dissipated" as the radiation you want? Spurs
and harmonics that you don't want are also "dissipated"? This is
certainly a possible definition of "dissipation", but I think a
definition which didn't depend on your feelings about the radiation
might be a better one.

>"Radiation" is the process through which the antenna converts the energy
>delivered to its terminals into a traveling EM wave in space. This process
>is "radiation", it is not "dissipation" nor is it "dispersion".

But "radiation" is also the mechanism through which a resistor sheds
the energy delivered to its terminals into a travelling EM wave in
space. EM radiation is heat in the process of being transfered away
from its source. Again, why would the EM radiation emitted by a
hot resistor be the result of "dissipation", while the EM radiation
emitted by the antenna is not the result of "dissipation"? What
happens to the radiation after it is dissipated (or not dissipated)
is pretty much identical in either case.

>The "dispersion" process that we have been discussing is what happens to the
>EM energy after leaves the antenna. Is it "dissipated" in space or is it
>"dispersed" in space?

Both the energy radiated by the antenna, and the energy radiated by the
resistor, ends up being "dispersed" in space. Why is one "dissipated",
and one not?

> Again, dissipation of the traveling energy infers a
>much different process than dispersion of the traveling energy. Dispersion

>in itself may be a poor choice of a word. "Spreading of Energy" may be a
>more appropriate term.

I don't think dissipation occurs as the radiation travels, I think dissipation is the process that created the radiation in the first place. What you describe above is what happens to both the energy radiated by the antenna and the energy radiated by the resistor. What's the difference between the EM waves emitted by the antenna and the EM waves emitted by the resistor, that one is dissipation and one isn't?

I think we've got to be on the same page by now. To be clear about the practical consequence of the differences in our opinions, my opinion leads to radiation resistance being as dissipative as any other kind of resistance, since it produces fundamentally the same result as any other kind of resistance, while your opinion appears to make some kinds of resistances dissipative and some not depending (solely, as far as I have yet determined) on your feelings about the resistance and the desireability of the radiation resulting from feeding the resistance power. I think my opinion makes a better definition.

> if the RF current is flowing, for any reason, then there will be a skin
> effect.

The key phrase is "current flowing". If current must be flowing, there must be a current path of some kind. For example a magnetic RF shield or a shield room relies on "eddy" currents. The shield doesn't work well unless there is a closed current path. The eddy current creates an opposing H field that cancels the impinging H field.

If the Faraday shield is open-circuited the wave is not absorbed or reflected but passes through very nicely as I described. If the Faraday shield is short-circuited the wave does not get through. It can only be because of the short-circuit current.

The boundary condition for tangential H fields between air and a conductor is that the difference is exactly equal to the value of the sheet current on the surface.

With respect to wave absorption, a quick look at all of my references seems to agree with your description of Chapman, but this is still bothering me. I will struggle with this some more and see if I can get it worked out. There is something wrong here about this reflection business. The same skin effect idea is applied to surface current flow and wave reflection.

It should be easy enough for the editors to check. Look up Maxwell nearly a century and a half ago and Heaviside a century back.

Or, if there's no satisfaction to be obtained from the ancients, why not set up a relatively small single-turn screened loop, tune it to 1.9 MHz and listen with an ordinary receiver. Then set up an unscreened tuned loop of the same diameter, listen with the same receiver and note whether there is any difference on the S-meter.

It makes me wonder whether any of you guru's ever had a radio receiver.

Reg.

One difference between the ir emitted as a result of heating and the rf emitted as radiation is that the ir is diffuse and contains little information, beyond increasing during transmit and then falling off. The rf, of course, follows the modulation more or less exactly. It also retains its frequency. The ir would be a broad group of frequencies that would increase slightly as the temperature rose. Maybe a useful way to distinguish dissipation from radiation would be the diffuseness of the resulting emitted energy.

Dennis Ferguson wrote:
"So what is the difference between the resistor and the antenna which makes one dissipative and the other not?"

Very simple. Efficiency is the percentage of the input to an antenna, system, or device that we are able to get out as the desired output.

An antenna usually radiates most of the energy it accepts. We don`t rate antenna efficiency on how much of the radiated energy is actually used, or even how much is properly directed. We rate efficiency based on how much of the energy fed the antenna is radiated in all directions and how much is converted to heat. Heat being the stuff which friction, for example, generates.

The antenna`s desired output is a radio signal. When 85% of the energy fed an antenna is launched into space and 15% is converted into heat, all the energy put into the antenna is gone. The 15% which wasn`t radiated was dissipated (wasted) because it wasn`t the desired output from the antenna.

Best regards, Richard Harrison, KB5WZI

Way back in the 1940's on several occasions I stood in front of a 50 KWatt, 3 GHz, pulsed radar parabolic dish when somebody switched it on.

In 1984 I stood in front of a defective CW, 1 KWatt microwave oven with open door and still working fine at 2.4 GHz.

My face felt slightly warm on all such occasions.

If on a hot day I face the sun I feel the heat.

On a cold day I notice the lack of heat.

So on a cold day I warm my poor old body at the gas fire in the living room.

On many occasions I have burned little holes in my fingers with electrical energy.

But I must confess my skin has the ability to detect only a rise in temperature. It gives me no clues whatsoever about the frequency of the electromagnetic radiation it is receiving. So I am obliged to accept radiation is all made of the same stuff. And as I am not a lossless transmission line it is all dissipated in me.

I was once within 15 feet of lightning striking the ground. I felt nothing. I witnessed only a small cloud of steam. I'm still around.

Dennis Ferguson wrote:
"I think my opinion makes a better definition."

I have no problem with Dennis` opinion except it doesn`t conform with the definitions accepted by a wide majority of those people who work with antennas. They`ve accepted the idea that an antenna has two resistive parts in series. These are the radiation resistance and the loss resistance. The same current flows through both. The radiation resistance is a fictional resistance that would take the same power as that which is actually being radiated were the fictional resistance to replace the radiation load. The radiation resistance is a voltage to current ratio in which the voltage and current are in-phase. It is not a resistor. It is a non-dissipative resistance. There is a difference between a resistance and a resistor, no matter who said otherwise. However, not all non-dissipative resistances are fictional contrivances of convenience. A transmission line`s surge resistance is not a resistor, but it opposes unrestricted energy flow in a line.

I have put up a Titan Challanger to compare it to a G5RV. Bought this used. Titan will not resonant on 40 meters, 12 meters, and its 2:1 on 10 meters. The G5RV outperforms on receive by 2 s units on most bands. Anyone know what might be wrong with the Gap or is this all there is?

MFJ is not going to manufacture the Hy-Tower as the Rohn Spalding bottom tower is no longer made. Probably the best bet is to find one used or taking the plans (from the instructions) build your own. A ham in the mid west found a Hy-tower sans the tower that had never been out of the box. He substituted a larger Rohn Spalding BX tower with good results. This was written up in Electric Radio Magazine.

Source record: 167981

I am in need of copies (or email copies
if you have scanner) for 3 article's
from old QST's.

Jan. 1983 QST, page 17. Automatic control for the Alliance HD-73 rotator.

Feb. 1996 QST, page 35. Build a Rotator
Pal.
and
Jan. 1999, QST, page 34. Rotator Magic.

What I am looking for is an article dealing with building a computer / rotor
interface. Thank's for any help as I
lost most of my back issues of QST and
CQ to a flood last year. I also know
about the commercially available interface's, but thought I would take a
crack at building one first to try and
have the fun of constructing it.
Please email any info to the address (s)
below.

"I was once within 15 feet of lightning striking the ground. I felt nothing. I witnessed only a small cloud of steam. I`m still around."

There is an old story which may explain Reg`s survival.

A priest and a nun were playing golf together. The priest was missing shots and muttering, "Damn it, missed again!".

The nun repeatedly chided the preist, warning him that God would not appreciate the intemperate language.

All of a sudden, there was a blinding flash of light and a deafening clap of thunder and the nun was struck dead. Out of the heavens came a thundering bellow: "Damn it, missed again!"

If you want height and strength with your J-pole use a wooden or pvc plastic rod that will slide into the J-pole and the mast. Leave about 1 1/2" space between the mast and J-pole. This will isolate J-pole from the mast. Have fun. 73 W9FPJ

It depends on the temperature of the resistor. If it is at or above
the temperature on our planet it will be in the infrared frequencies,
or light frequencies if you get it hot enough to glow. In space it
could be cooler, and the frequencies lower. Also, if it radiates
like a black body the spectrum will be pretty broad-band.

While you are at it, look on the amsat.org website and got to the files section. Look for a program called fodtrack. It is a free program for tracking the sats. While you are not interisted in the sats, there is an interface using a parallel (printer) port of the computer in the file. You may want to look at how he uses the parallel port and a A/D chip to control the direction of the rotator.

I've done that doezens of times Reg, and there is absolutely no
difference if you leave a gap in the screen.

If you close the gap, the loop goes dead.

There really isn't anything amazing about this, except that some
people somehow think the screen makes the loop immune to EMI.

Now a thought like that is amazing.

I'm pretty sure it is not infrared, but I'm remembering this from Mechanical Engineering school a long time ago so feel free to consider it suspect. The sun's radiation spectrum peaks in the visible region so the intensity of infrared is way below light, and CO2 is opague at infrared so that not much of what there is makes it to the surface. The power density at infrared is very low. The surface of the planet is heated by the light and reradiates in the infrared, but the CO2 also absorbs the outgoing infrared and keeps the planet warmer than it otherwise might be.

I don't know about ultraviolet, but it may be that the skin isn't fully opague at ultraviolet so some of the heating is going on below the skin where you haven't got any nerves. You can definitely feel a visible light laser beam, you just have to have one at high enough power. The lasers that are below a couple of hundred mW are harmless, but we had a 5 W argon-ion laser (2 colors at the output, green and blue, nothing anywhere else in the spectrum) that felt kind of like a bee sting after a second or two on the skin, and which would burn pinholes in your clothes or set fire to paper if you weren't careful.

Will MIR's fiery descent produce a long enough and persistent enough ionized column of air such that something akin to meteor scatter will be possible in the Pacific? I've wondered about the same thing while watching the Shuttle re-enter at night. The ionized trail behind the Shuttle lasts almost a minute. The MIR should break apart and leave many burning trails...

How does a resistor increase the frequency of the EM energy?
Is there a local oscillator inside?

Seems to me, there's not much of an energy conversion going
from electrical energy of a certain frequency to EM energy
of the same frequency.

From your photos it looks like it would not be difficult to mount a vertical on top of one of the two metal supports for the seat back fabric. If you are willing to put a gromet (brass, or even better a nylon one if you can find one) in the weather fly, you could run the antenna through the grommet without compromising the weatherproofing significantly. If the gromet were at the base of the antenna (touching the mount, i.e. ground) it should not adversely effect the antenna.

>Is there a local oscillator inside?

This is where my physics gets weak, but I think thermal energy
manifests itself as molecular agitation and the radiation is
caused by the accelerations and decelerations of (the electrons
associated with?) the vibrating molecules. The frequency is
telling you something about how the thermally excited molecules
are moving. Contrast this with how the "good" radiation is
generated, it is still generated by the accelerations and
decelerations of charges but we use an electric potential
to move them instead.

>Seems to me, there's not much of an energy conversion going
>from electrical energy of a certain frequency to EM energy
>of the same frequency.

No, I think the conversion process is the same, that is we're
converting the kinetic energy of charged atomic-level particles
into radiation. It is only how we get the particles moving that
is different. In one case we control the frequency, in the
other case God does.

I'm not sure about this, however. I was hoping someone might
know enough to address this, since the fact that "good" radiation
is coherent while thermally-generated radiation isn't still
bothers me. I don't see how that matters to the thermodynamics,
but it might.

I found the reference that I was looking for. It is Kraus "Electromagnetics. 4th edition" pages 556-559. I will scan the pages and email them to you or anyone else who wants them.

The idea is that if a plane wave in air strikes a metal surface *of infinite extent* (explicitly mentioned twice) such that the impedance in metal is very small and the impedance in air is 377 ohms, the wave is totally reflected and a pure standing wave is set up in air. The boundary conditions are that the tangential E field is zero and the tangential H field is doubled. This is completely analogous to a shorted transmission line that reflects the arriving wave. But for this to happen the conducting plate must support a sufficient current flow, either by being "infinite extent" or by having a closed path such as a magnetic shield structure of some kind.

Walt,

The (I assume) fiberglass mast shouldn't be any significant problem. The flag (either plastic or cotton) should also have little or no effect even when wet. Small and generally insignificant interactions may occur from time to time depending on the moisture or insect saturation levels of mast and/or flag. 8-) Install it, use it and enjoy.

Hi
Would anybody help me for selecting a suitable VHF wireless microphone?
Because I am using a SONY WCS 900MHz wireless microphone for voice pickup of the speaker during the meeting or sharing, but the performance is not satisfactory.
It is always interfered with the noises, even the distance between the transmitter and receiver is less than 1.5 meters and I have already tested the performance of three sets of this product, the result are the same. Not satisfactory.

I am now want to source for another set of Wireless Microphone (VHF). Would you please refer to the following working condition and the product information to give me some comments and advises?
Does the power of the transmitter have significant difference for 20mW and 50mW for my application?

Hi
Would anybody help me for selecting a suitable VHF wireless microphone.
Because I am using a SONY WCS 900MHz
wireless microphone for voice pickup of the speaker during the meeting or sharing, but the performance is not satisfactory.
It always interfered with the noises, even the distance between the transmitter and receiver is less than 1.5 metres and
I have already tested the performance of three sets of this product, the result are the same. Not satisfactory.

I am now want to source for another set of Wireless Microphone (VHF). Would you please refer to the following
working condition and the product information to give me some comments and advises?
Does the power of the transmitter has significant difference for 20mW and 50mW for my application?

Woking condition: The maximun distance between transmitter and receiver is under 10 metres.
It may have one or two concrete wall and
peoples seperating from the transmitter and the receiver.
Portability: can use bettery for both
transmitter and receiver.

Product 1: SAMSON Camcorder VHF wireless microphone
Transmitter : model VT3L, RF Power 20mW;
Receiver: VM1 Double antenna,Single Conversion Super Heterodyne Diversity
(I don't know whether it is true diversity or phase diversity and the actual performance between these two),

sensitivity: =<6 micro volt @ 20dB S/N
Product 2: SHURE Camcorder VHF wireless microphone
Transmitter : model T1, RF Power 50mW;
Receiver: Non-diversity single antenna,
sensitivity: -109dBm (0.8 micro volt @ 12dB SINAD)

I will not consider to buy the following product, because it cannot use bettery for the receiver unit.
But do you have any comments for the comparison between product 1 & 3. Since there is only the difference between the
Receiver Sensitivities and with the same transmitter unit VT3L; and I had the experience (very good performance, with any noise)
in using a OLD model SAMSON VHF wireless microphone which is nearly the same as the product 3.

Product 3: SAMSON VHF wireless microphone
Transmitter : model VT3L, RF Power 20mW;
Receiver: VR3TD Double antenna,Single Conversion Super Heterodyne Microprocessor True Diversity
sensitivity: <3 micro volt for 20dB SINAD, < 10 micro volt for 50dB S/N

I would think so. No different from any other chunk of metal really. Man made or not. I've watched the shuttle fly over here a couple of times at night. Very awesome looking. I could see the plasma trail all the way from horizon to horizon as it passed from west to east. I could see the front of it glowing white hot. Looked like an airliner on fire from the distance. The plasma trial glowed a pinkish color and lasted quite a while before it dissipated. I'd say about 20-30 minutes in the case I saw to the north. I had it fly directly over another time at night, and could faintly hear it. And it was way high, doing about 10,000 mph at that moment. It made a faint humming sound from the wind noise. MK

> Don't use a metal mast.

If the antenna had a common mode problem, it would just use the coax shield instead. So the lack of a metal mast not a real fix unless he's talking about one of these "hang off the side of the mast" jobs. Best way to go is keep the metal mast for the lightning advantage, and use a decoupling section on the j-pole. Some of the j-pole versions seem to show better decoupling than others depending on the matching and feed scheme. If a standard j pole has problems, you can always add decoupling.

> >fed vertical 1/2 wave antenna to be 'ground plane or metal mast
> >independent'. Is this talking bullshit?

Not really. What they should be saying is their antennas are well decoupled from the feedline. Only if the antenna has poor decoupling should the mast really be a problem . The height above ground will show more an effect on the pattern. And if there were no decoupling,and you had a common mode problem, you could have a wood mast and still have problems. It will just radiate from the shield of your coax. Very few common 1/2 wave designs have decoupling sections. I've never seen a single J pole design that did. Nor do most of the gamma loop fed versions sold. "ringos". But AEA did make one for marine use a few years ago that did have a decoupling section. I think it used sleeves if I remember right. With 1/4 GP's the more radials, the better decoupling, and also you can add a second section below to clean up whats left.
> >
> >Is the only way to use a vertical dipole instead, mounted on the side of
> >the metal mast as below, in order to avoid coupling? I understand the
> >distance from the mast shall be chosen for minimum radiation pattern
> >distorsion.

I'd never want to mount a vertical on the side of a mast unless a specific reason such as mounting dipoles in phase to get gain in a

direction. For omni use, I'd mount on top of the mast. I usually use base fed 1/2 waves.
You can add decoupling to any 1/2 wave vertical. And there are more than one ways to do it. One method I tried which seemed to work pretty well was a set of 1/4 wl radials a 1/4 wl below the feedpoint. The radials are grounded to the shield of the coax at that point with a union. I think you could also probably place chokes at thew correct points and do the same thing. You also have the sleeve or cones that can be used instead of radials. MK

The R3 used a remote tuning box, and a motorized tuner at the feedpoint.
20-10m. A friend of mine had one. Was a pretty good antenna. The R5 and
later versions all were tuned using stubs etc. No remote control box.

Much is mailed across the Atlantic - both ways - and never arrives.
However, we now have the technology, so in order to support this
discussion I have temporarily quoted the relevant excerpt as a PDF which
is downloadable at http://www.ifwtech.com/g3sek/misc/skin.htm

I am not an EM physicist, but Davidson's derivation appears to show that
if an RF current is flowing across any arbitrarily small part of a
conducting surface - for any reason - then there will be a skin effect.

Davidson's derivation is far more general than many published in better-
known textbooks:

1. It only requires that an RF current is flowing at the surface, but
does not require to know why, it shows that the skin effect is not
exclusive to any particular type(s) of circuit.

2. Also, unlike some derivations (e.g. Terman) which assume a round
wire, Davidson's requires no special shape for the conductor (the
analysis area is assumed to be flat, but this is not a restrictive
condition because that area can also be made arbitrarily small).
Derivations such as Terman's remain valid, but are subsets of Davidson's
more general proof.

Since Davidson (if I interpret it correctly) has provided an independent
derivation of the skin effect, it can be taken as a "given" in analysing
the behavior of a circuit. Thus one can drive an analysis such as Bill's
"backwards" to establish/confirm what must therefore be happening in
terms of electromagnetic induction.

Mark,
Like most antennas, get it up as high as possible. The real
trick is tunning it. The bar and plate under the coil is adjusted
closer/further away from the coil until you find resonance, or the
lowest SWR possible. It's very 'touchy', and it'll change when
it's at it's 'in use' position. Just keep makeing small changes
till it's 'right'. Have fun...

That's about the way they work.

Verticals require a good ground system when near earth, plus the
antenna has other efficiency problems.

Depends what you mean by 'constant impedance'.

Strictly speaking, there is no such thing as constant impedance. Every medium, juncture, and termination in a transmission system has a frequency dependent impedance. What seperates the good devices from the poorer ones is how badly the impedance varies over the intended frequency range.

Another question that has to be answered is 'how good does it have to be"? In television applications, impedance match is very important, as even very small time-delayed reflections can result in visible 'ghosts' in the picture. In our ham radio communications environment, we seldom have such rigid requirements, and the most important goal is usually just to transfer as much of the energy as possible accross the connection.

The "F" connector was invented over 40 years ago by the Cable TV industry as an inexpensive connector for 75 ohm coax. To the best of my knowledge, 75 ohms is a practical part of the definition. "F" connectors come in many types & variations, just like any other coaxial connector. They are commonly used in CATV applications up to 1 GHz with return loss of 16-20 dB. Once again, it depends on the type and quality of the individual connector.

My dad always told me, "You get what you pay for." I guess since Tripod is free, you can't complain. I keep several pages on Tripod...never had a bit of trouble. I also keep every file on Tripod's site on my computer just in case there is ever a problem. Haven't had to use the backup plan yet and I've been with Tripod for about 3 years now. I guess it's a "sign" you should keep backup files of everything on your computer anyway. You HAVE been doing that haven't you? Ever "lost" anything on your computer at home?

I'm not sure, but I don't think Maxwell's equations differentiate
between electrical energy and EM energy that are coherent.

But Gary, that's NOT electrical energy and EM energy OF THE
SAME FREQUENCY. I'm talking about accelerating electrons
to generate photons coherently.

5451. coiled dipole

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-21 14:39:26 UTC
From: "david s." <david@hedgewoodhomes.com>
Message-ID: <y23u6.4829$%N.27660@skycache.prestige.net>
Source record: 167927

okay I am looking for pointers and comments on an antenna that I am going to build so here are the specs

I am going to use a piece of cardboard concrete form that is 12" in diameter and 12' long.(this is just for shaping the antenna) 3' circumference and 72" on each side.
I am going to use 14awg bare solid copper
250' of 14 awg wire 250'/2=125'/3=41.667 72/41.667= 1.73
1" pvc frame to support the antenna once it is installed.

starting in the middle of the tube I am going to wrap 125' each side around the tube keeping the wraps spaced as even as I can for a total wire length of 250'. if my math is right should mean that the wire coils should be about 1.75 inches apart.

now many might realize that the wire is the right length for a dipole which is where I am getting my dimensions from however I do not have the room to put up a dipole I can put up something that is about 12' long and be horizontal.

I am hoping to use this with my Kenwood ts-450s/at I know the antenna is just a compromise but can anyone tell me if it will work won't work what problems I am going to encounter? will it work on all the hf bands? anything I should change? is it a crazy hair brained idea?
comments please

I think that we are dealing with two issues here and an application of terms
in a manner generally accepted by those in the field. The question above
was presented to discuss the second issue, which is understanding the

process through which EM energy is spread out as it travels away from the antenna. In understanding "path loss", it must be understood that at any distance, the total energy in the EM wave, as measured over a sphere surrounding the antenna, does not decrease. From this perspective, there is no "dissipation" occurring as the wave travels.

I understand now that your use of the term dissipation goes back to the first issue which is the radiation process. I will address below ..

> The answer is that the power is entirely radiated in an EM field,
> whose spectrum depends on the temperature of the resistor. If you

Now we are at the first issue.

I understand your position that total energy is conserved in one form or another. I agree that in the case of the antenna, the thermal or IR energy it creates can be detected away from the antenna so it could be considered to be "radiated". This "radiation" however is not the form of radiation as defined by general antenna theory (gain, radiation patterns, etc). This is considered energy lost or dissipated because it is no longer in the form or at the EM frequency of interest. One distinction here is the fact that to detect this energy you do not use another EM antenna. Thermal heat you can detect with your skin. IR with the goggles you mention. Radiation of energy in this form is not the intended function of the antenna. The antenna's performance characteristics are not described to account for this radiation (except for the definition of radiation efficiency). The antenna does not perform in a reciprocal manner (transmit and receive) for this type of energy.

The real distinction here is that the EM energy radiated by the antenna is not irreversibly lost through the EM radiation process. The antenna will detect the EM energy as it passes by. It is functioning as an antenna.

The use of terms "dissipation" and "radiation" in this manner is generally accepted in the industry to account for the distinction in the antenna's behavior relative to the EM and thermal or IR energy. I don't disagree with your discussion of heat and IR. We simply apply the term dissipation differently.

>
> >> Irreversible processes are dissipative processes. The decrease in

>
> Dennis Ferguson

Again, the distinction goes back to the antenna's reciprocal ability to radiate and then detect the EM energy. Think of the distinction this way. Apply an EM voltage to an antenna, EM energy is radiated, it travel to another antenna, this antenna detects the EM energy and it develops an EM voltage at its terminals. Apply an EM voltage to a resistor, thermal and IR energy is created, this thermal and IR energy travel to another resistor, does the resistor detect this thermal and IR energy and convert it into an EM voltage? This is my distinction between dissipation and radiation.

You will have some interaction, but as long as you can get some reasonable separation of at least several inches between the antenna and the tube frame you will be all right. The frame nearest the antenna could result in a "nulling" effect in the direction from the antenna to the frame tube. If you could relocate the mount to the highest point on the bike and ground everything, you would do better. Rather than a flag, what about a separate antenna mount farther back, or even way up front? You could even mount a safety strobe on the pole. Maybe even a neon bulb that would blink when you talk! Do you have a trailer for your bike? Mount the antenna on the trailer and put your big battery and amplifier in the trailer. You could even install a small beam. Carry a charger with you and plug it in when you stop at gas stations and restaurants.

Seriously though--thanks for the bike post--it reminds me that I better get busy and rig up my bike rack mount for the upcoming Kal-Haven Trailblazer ride in May. Now, just where to mount that Mirage B1016G amp and big deep cycle on my full suspension Cannondale Super V.....actually I am going to simply put a trunk lip mount on an aluminum QD luggage rack, fashion some sort of mount to hold a 4 or 7 AH SLA battery on the rack. I am either going to carry a VX-5R in a chest harness and run jumpers, or separate and attach an FT90R to the luggage rack and handlebar with a small remote speaker. Since this is a railroad bed trail and very flat and straight, I may do the latter.

Source record: 167926

Another experiment -

The 'screen' or 'shield' does not need to totally enclose the main loop to produce identical effects.

If a single wire is run very near and parallel to the main loop, when the wire is open circuit it may just as well not be there insofar as reception of radio signals is concerned, just like the totally enclosing and open circuit screen.

When the wire is shorted to form another continuous loop the main loop becomes dead. It too behaves as a shorted turn, just as it does when the totally enclosing screen is shorted.

As Tom and others have said, the effect of the braid when an inner coaxial conductor is used as a receiving loop is to ensure the capacitance coupling of the loop to its environment is balanced about its neutral point. When the loop is in the vertical plane this ensures no signals or noise which arrive from the broadside directions are injected into the receiver. The screen ensures the bridge is balanced as in any other sort of capacitance bridge. The null is sharpened as when both magnitude and phase are adjusted for a balance.

As has already been said a well-designed loop out in the open does not need a screen. It's better to use the coax braid as the main loop and leave the inner unconnected.

I have to agree, I have had many problems with ISP (used to cover all the net stuff), and none ever owned up to being the cause of the problem. These folks

are to be praised for their honesty, not flamed. As I tell the students here, "you will make many mistakes, the only people that never make mistakes are those that never do anything".

5457. Beam antenna SWR changed!

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-21 16:18:11 UTC
From: Rudy Marcelletti <rudym@net-link.net>
Message-ID: <3ab8d45c$0$62143$bbae4d71@news.net-link.net>
Source record: 167930

I have had SWR changes on beam antennas lately. One antenna is Cushcraft X-7 with a 40 meter element kit (separate RG-213 coax feed and coax choke). The SWR on the 40 element is fine. The triband X-7 has 75 ohm &#65533;" CATV hardline feed with either 9913F or RG-213 jumpers. The X-7 has the Cushcraft match box choke. This antenna is at 100 feet. The other antenna is a Highgain TH3JR 3 element tribander at 50 feet. It is fed with RG-8 type coax. This antenna has a coax choke.

Both antennas have acceptable SWR on 10 meters. The X7 is 1.1:1 or lower at 29.000 MHz. The TH3JR is about the same. Neither antenna uses traps on 10 meters. Both antennas are now SWR of 5+ at 14 and 21 MHz.

Moisture in traps? The Highgain antenna has traps on all three elements, the Cushcraft antenna only has traps on the director element. We have had a lot of rain and wind lately. Perhaps a some traps have been moistened. Should I heat them with an amp!!!!

If I had feed line problems I don't think I would get good SWR on 10 meters--it would be bad everywhere.

I was thinking maybe something came loose, but on both antennas on different towers at the same time?

Any suggestions?

5458. Are Screwdriver plans still available.

I see that Mr. Johnsons site is down, and I would like to order plans from him on his screwdriver. I would like to try my hand at building one. Or has anyone the plans that you dont need anymore.

The ones forsale are a bit steep in my opinion (not that its worth much), so that is not an option, besides I like to roll my own.

On Mar. 17, 2001, 3:09am, Tom, W8JI wrote:
"Despite using a shielded loop, a FSM can indicate the electric field because it is INSEPARABLE from the time varying magnetic field."

No, The FSM can measure the magnetic field and because the relationship between E & H fields in space is fixed, if you know either one, you can scale the presentation in terms of the other. It is no more complicated to present volts per meter than using a current meter to read volts.

The declaration that electric and magnetic fields are inseparable is wrong.

Our experience tells us the opposite.

Our experience tells us that audio and power transformers can have strong external magnetic fields even when surrounded by non-magnetic conducting materials. High-permeability "mumetal" shields are used to enclose transformers to keep high-intensity magnetic fields in or out, but non-magnetic materials do not block magnetic fields.

We don`t mount the input transformer of a high-gain audio amplifier anywhere near a power transformer. Why? Because the non-magnetic conducting material around the transformer has little effect on the magnetic field. Even magnetic material has to have high-permeability and be ample to provide effective magnetic field shielding.

Our experience tells us that non-magnetic conducting materials do prevent capacitive coupling of signals. We use shielded wire, coil shields, etc. to keep unwanted signals in or out.

Grounded conducting material between transformers terminates capacitive lines of force at ground potential thus avoiding capacitive coupling between the transformers. Capacitive coupling between other signal or noise sources are likewise ended by a grounded shield. Capacitive shielding just does not block magnetic coupling without additional magnetic shielding.

These experiences are likewise applicable to the shield on a loop antenna with some adjustments. Debates about practcability are odd given the ample examples around.

Best regards, Richard Harrison, KB5WZI

Saw this posted in the local news, and was wondering if we will be able to see the thing at nite, day, or at all, we live south of San Antonio,Tx.????? thanks for any and all input. news release below.

Russia sets Mir dump for Friday
MOSCOW (AP) - The Russian space agency on Tuesday issued the precise timetable for dumping the Mir,
saying the 15-year-old space station would be brought down into the South Pacific on Friday with a six-hour series of measured engine firings. After Mir descends to an altitude of 132 miles by early Thursday, Mission Control will switch on the station's computer and align Mir for descent. If the sometimes-unreliable computer and its orientation system work as expected, a Progress cargo ship docked at the station will fire its engines twice for about 20 minutes, around 3:30 a.m. Moscow time (7:30 p.m. ET Thursday) and an hour and a half later. Around 8 a.m. Moscow time (midnight Thursday ET), Progress engines will fire again to send the station hurtling into the ocean between Australia and Chile. Most of Mir is expected to burn up in the atmosphere, but up to 27.5 tons of debris are expected to reach the Earth's surface.

Hi Cecil,

The deceleration of charge is through the physical interaction at the atomic scale. The bulk of mass has its energy state elevated above the ground condition and it returns to the ground condition through the radiation and dissipation of that charge boost by emitting IR (or actually a spectrum of wavelengths consistent with a black body radiator). The wavelength is dependant upon the energy levels and the de Broglie wavelength of the electron that eventually releases the photon.

de Broglie is the oscillator you are seeking.

The more energetic the stimulation, the more blue content in the spectral emission, extremes of blue leave the range of visual perception to become ultra-violet and then progressively more energetic toward X rays.

When this interaction occurs, electrons are moved out of their ground state contingent upon the atom they are circling. Some electrons are elevated higher than others due to this dependency. Within a body of complex molecules there are an array of different electron orbit changes that all collapse back to their ground state and contribute to a wide spectrum emission (dare I say radiation or dissipation?).

Consistent with conventional language and most of science:
Energy in - Energy out - dissipation.
And of course, the IEEE is hopelessly unable to pursue this discussion.

as for:
>Seems to me, there's not much of an energy conversion going
>from electrical energy of a certain frequency to EM energy
>of the same frequency.
You've been using that IEEE crutch too long. Where does it describe that the product of a conversion is identical to the input (in other words: what does conversion mean to you?).

The 6M hamstick is not worth the trouble.
The one I had suffered from narrow bandwidth and the lock nuts
never really wanted to keep it locked.

For six there really is no reason to have a loaded antenna.

I used a split ball mount a combination of heavy duty/medium duty
springs, a 3" extension and a whip tip adapter to make my mobile
antenna.

It works well on 6M and 2M of course.

http://www.dbbear.com/k0emt

Then check out mobile under projects.

I have had great success working DX with the Antron 99.
The base of the antenna is about 10' above ground.
The Kenwood TS-570s feeds the antenna via 9913.
(Yeah, I know it's overkill.)

The 570 can tune the A99 from 6Meters to 17Meters.
It performs best on 10,12 and 15.
Performance on 6 is marginal. It is basically deaf 20M and below.

Btw, there are radial kits made for this antenna.
I have not tried any of them, and I don't know of anyone that has.

I hope that helps.

Tom, W8JI wrote:
"If you close the gap, the loop goes dead."

Now, that is a common experience. You break the shield on a cable and the conductors it contains can communicate with the world outside.

The shield on a loop must be open to avoid current in the shield. That is a feature of Faraday screens. They are broken to prevent induced circulation throughout the screen.

Induced current in the shield creates a field which opposes the incident field (Lenz).

Put the action and reaction together on a cable shield and not much is left on the inside of the shield.

Hi Steve,

Forgive me, but your statement above is downright provincial. You are simply ignoring the field that your antenna theory was derived FROM: Optics.

Due to the wavelength nature of the translation of energy, you are not allowed to abandon Infrared to the sphere of astrology simply because of scale.

Rudy,
From what you describe, you may be correct about water in
the traps. It sounds like the antennas have the problem, not
the feedline. Using an amplifier to 'dry out' the traps isn't
the best idea in the world. Best would be to take the beams
down and look at them, it may not be the traps. (That's easy
to say, I'm not the one climbing the tower!)

The Appendix that you sent is quite routine. I have several references that
do pretty much the same thing. I don't see anything extraordinary about it.

About reflection:

Suppose that some fraction of an HF wave is striking a plate whose dimensions
are the same. As the E and H fields oscillate just beyond the surface they
cause electrons in the plate to set up various oscillating Ec fields (due to
charges), and therefore oscillating currents Jc (due to charges), inside the
plate. Recall that for every Jc there must be an Ec (Ohm's law).

These are required in order to cooperate with the incoming wave in order to
satisfy the boundary conditions (tangential and normal) for the incoming E
and H fields at the surface and within the body of the conductor.

We can see how these local induced currents can provide the "current for any
reason" that can create a reflected wave. The basic principles are:

1) induced E and H fields that are not allowed to exist in the plate are
reflected in order to satisfy the boundary relations for E and H fields at
and inside the plate

2) the induced currents create the reflected wave (it doesn't just "bounce"
off the surface)

3) the strength of the reflected wave is just enough to satisfy the boundary
conditions, and this is equivalent to almost "total reflection", allowing for
losses in the plate.

The plate is a short-circuit for the wave.

We can also see that the current flow obeys the rules of skin effect for
current, which is identical to the skin effect for reflection. These same
currents reverse the penetration.

My text "Fundamentals of Electric Waves by Skilling (prof at Stanford, 1948)
discusses this very elegantly, although it has taken a lot of struggle to dig
it out.

Also, I stand by the thoughts that I have presented on the subject of the
Faraday shield. I also stand by my comments on magnetic shielding. Terman
agrees on that subject.

Finally, the material from Kraus that I sent you is OK. To get an absolutely
complete reflection of the *entire* infinite wave front, the infinite
surface is mandatory. In the subject we are discussing here, only the part
of the wave that hits the plate is reflected.

I tried to obtain a rotating spit but couldn't find a willing
manufacturer.

However my experiences exposed Dr Joseph Goebbles' lie, designed to demoralise British radar engineers and technicians, that exposure to high power centimetric radio waves caused sterilisation of the testes. It also became apparent that Goebbles was not taken in by BBC lies that RAF night-fighter pilots took to the air chewing raw carrots.

I made a j-pole by shortening a 102" radio shack whip (cb) to 77" and forming a 19" one-inch spaced matching section at the lower end (locally heating the stainless until red with a propane torch, and hand bending). I would mount it on your bike by clamping the antenna to the rear sock support with metal clamps. I'd feed the stub somewhere about 5" up from the bottom of the "U" section with the coax (moving it as necessary to where it's matched). A couple of coils in the RG-58 A/U coax feedline will serve as a balun. This is an effective antenna I've used on single and tandem upright bikes. I've got a Green Gear Sat-ur-day which is so far no-radio. 73, Jim W5AI.

Hi All,

The problem with trolling, is you never know when the troll is
working, or simply posting.

What is described above appears to be yet another old wive's tale
embellished with imaginative "lies" from the nazis.

The danger of RF radiation is that it is NOT always perceived as
warming. In fact it can be perceived as cooling!

However, neither of these sensate conditions is very useful as an
indicator of dangerous fields. Why? Because the core of the human
body has very few nerves that distinguish temperature (why would
they?) and by the time your skin can detect a deep cavity temperature
rise, your goose is cooked.

There is a vast difference between being warmed by the sun, and being
warmed at the open door of a malfunctioning radar range.

Punchinello was simply lucky, others have died for lack of that same
luck.

I see another important difference, related to the coherence or randomness of the radiation: the infra-red energy so emitted can't be collected for use except by a lower temperature system that it might shine on. The rf energy can be collected by a system at the same temperature as the transmitting system. Thus you have a system of energy transmission just like a rotating shaft (well, maybe a little lossier) or a laser beam (well, maybe not as well focused).

The G5RV is 100 feet long and is fed in the middle. YOu will need some space slightly longer than 100 feet to support it and and few feet on each end for what you use to hold it up with.

Let's for a moment assume your perspective is right Richard, and as you keep saying we can shield a loop and alter the response to time-varying electric fields from sources more than a few loops diameters away.

Let's assume the hand-waving works, and the electric field response vanishes like magic...and that Reg, Bill, Roy, Bart, and the rest of us are totally wrong.

Now, tell me what you gain with the hand-waving. How does that "magic" help the user of the antenna hear a signal and through the noise from next door?

It's not how long the wire is, it's how much area the antenna covers
and how you distribute the current over that area that matters.

If you pack 10,000 feet of wire in a ten foot linear area of sapce,
you have a ten foot long antenna....not a 10,000 foot wire. You do,
however, have the loss resistance of 10,000 feet of wire acting with
the current distributed in the system.

That's why fractals, electric heaters, and light bulbs have coiled or
zig-zagged wire wound in larger coils. They try to pack as much
resistance as they can in a small area. They are interested in
generating heat and loss, instead of signal.

That's also why the best electrically small antennas generally use
the least amount of wire possible to achieve resonance.

I'd plan on doing something else.

Hi John,

There a couple problems here. One, the issue of:
> the infra-red energy so emitted can't be collected for use except by a
>lower temperature system
is simply the conventional signal to noise ratio imposed on all data
communications. This is not a property of the sender. The
conventional fix is to cool the detector.

Another point is with your
> related to the coherence or randomness of the radiation
which, again, is not an issue of the source, but rather the load (in
this case, I presume, a matter of the loss in an antenna) where
elsewhere in this thread you mention:
> contains little information, beyond
>increasing during transmit and then falling off.
This last statement is simply the revelation of the pulse (transient)
response of the load (the loss in the antenna) to which the energy is
applied. In other words you are describing the output of a low pass
filter, not its input.

If you want the IR to follow the modulation faithfully, lower the
thermal mass (raise the roll-off frequency of the low pass filter).
Useful IR data bandwidth encompasses the entire VLF to SHF spectrum
easily and is used everyday to communicate data approaching terabit
speeds. There is nothing in the cards to make IR inferior as a
communications frequency.

Part of this I can agree with, and part I must disagree with. Learning Morse code is actually a fair price to have to pay; not because I had to pay it or because anyone else had to pay it. It is a fair price to pay because that is what is required (at least for now). That may change in the near future. You can't go to Wal-Mart and say, "I think the price for this doohickey is too high, and that isn't fair. You need to give it me for less." When you go to Wal-Mart and see something you want, you either dig through the pocket lint to find enough money to get it, or you tell yourself it's too high a price and wait for them Rollback the price. Either that or you try to steal it and get nailed by the little old lady at the door. You can stand there and gripe at them for their outrageous asking price until your face turns four shades of blue and your head falls off. It doesn't matter. You don't get to set the price. They do. So, you just have to decide what you willing to pay. The very same principle holds true for amateur radio.
I'm not advocating one side over the other. Personally, I paid the asking price at the time. I started out as a no-code tech, but I sat down and studied the code and passed it, albeit at only 5wpm. I know there are those out there who say I am no more of a ham than they consider the no-code tech (it makes no difference that I was in the process of studying 13wpm when the current restructuring went into effect). I have a very dear friend who moved about 100 miles away making contact via 2m quite complicated I keep hounding him to upgrade, but he just won't do it. He plans to wait until they drop the code requirement completely, and that is his right. The price right now is too high. That's his decidsion. You have to make yours.

The above is just an opinion, and do you know what they say about opinions? They are like @ssholes. Everyone has one and they usually stink.

I've had an old R5 vertical in storage for quite a few years and recently took it out for a re-furb and to use at my summer cottage. After downloading the instructions from the Cushcraft manual site, I realized that my R5 doesn't look anything like the one in the instruction manual. My trap assemblies are much different than those shown in the manual. Most notable is the 20 meter section which features a trombone-like tuning stub rather than a straight tube like is shown in the manual. Can anyone shed some light on the model I have, or maybe point me to an online manual somewhere?

Thanks,
TH

Hello, Jan

Try an OSJ (Open Stub J-Pole)

If properly made, it is not effected by mast length, or if it is even mounted
on a mast.

The trick is the right combination of element lengths and spacing.
Spacing being very important.

I have seen so many J-Pole plans that say the spacing is not too
important because you can adjust the feed point for a 50 match.
It is like putting a band aid on a bad design.
It's still a bad design.

I don't want to start a fight here, but just in case I have my flame suit on.

So build a better J-Pole <A

"There is a vast difference between being warmed at by the sun, and being warmed at the open door of a malfunctionng radar range."

I believe Radar Range is a Raytheon trademark, but we know you mean microwave oven.

Richard Clark makes a good point and I`m relating this story as an advisory.

About 50 years ago a radio amateur friend of mine, Norman, W5OQJ was experiencing chest congestion related to a winter cold..Norman was a very close friend and his wife was actually one of my cousins.

Norman was a projectionist at the local cinema. So, during his evening shift he decided to bake out his cold using radiation from the projector`s arc lamp. He may have bared his chest to one or the other of those projectors for perhaps hours.

After closing the theater and going home to bed, he woke up dead. I guess he was ultraviolated by the arc between those carbons.

Overexposure to ultraviolet is a baaad idea.

Best regards, Richard Harrison, KB5WZI

Hi Dennis,

You have a mix of problems here.

For one, the assertion that IR is of no consequence from the Sun is dreadfully overstated. IR encompasses a very much broader range of wavelengths than the range of those that are visible. The Solar spectrum does peak in the visible, but the lowest IR wavelength radiation levels (at the surface of earth) is only down from the

visible peak by about 1 or more dB. This level is on the shoulder of a roll-off, but out another 300 nM the level is still down only about 4 dB. If we were to go further into the IR, we would find levels down only 6 dB 1000 nM from the upper edge of IR. The range of visible light is down 3 dB over an interval of only 200 nM. Thus, in their separate power bandwidth, IR still manages to be as bright as the visible Sun.

This includes the holes in the radiation spectrum due to the various constituents in the atmosphere. However, CO2 hardly makes an appearance until we get into the very deep IR where the Solar spectrum has already declined to a small level. The green house effect you describe above is called a red-shifted response where the applied power was at a shorter wavelength than the product wavelength. More appropriate to the discussion are the optical densities of O3, O2, and H2O which figure far more in the attenuation of power. Even so, what power is subtracted from the power bandwidth is largely confined to narrow band reject regions until you push out to 1400 nM.

And then there is the discussion of "weak" lasers.

The level of radiation from the Sun on the earth's surface, at the equator, at noon, on the equinox, is at least 100 mW/cM**2 for this complete black body spectrum. A laser beam is roughly 4 mM**2 and the ones (HeNe & LD) I am used to push about 5 - 10 mW into that area. Comparing the Sun to the Laser, the Laser is illuminating an area with roughly the same power as the Sun. HOWEVER, this power of the Laser is confined to a spectrum of maybe 10 nM wide, the Sun is 2000 nM wide. The Laser is thus radiometrically 200 times brighter than the Sun's red constituent when equal bandwidths are considered.

The reason why Cecil and I (and many tested for just this possibility) have never felt the radiation of the Laser is not because it is too dim at that (HeNe) color compared to the Sun. The answer is that man is not sensitive to that color - that's all. Now if you up that ante and lower the wavelength to the blues and ultraviolets, the far more energetic emissions will cause tissue damage whose wounds may feel like burns (or then again, maybe not - but damage is there all the same).

The shift of wavelength from red to blue imparts enough electron Volt potential to a target to begin to work on matter at the atomic level (stripping of electrons from orbits). The longer wavelengths are confined to perturbing molecules without changing their chemistry.

Hi Richard,

You may remember fire watch duty in the navy. In the shipyards fire watches had to stand by the welders, but they couldn't watch. They were warned to only glance and also to not look at the walls. The arc (gas or electric) is very blue intense and the reflections off the white walls (or even gray) are very hazardous to vision.

Those who ignore these simple cautions were regularly admitted to sick bay with UV burns of the retina which "felt like sandpaper." The condition would pass in 4 hours to a couple of days. You only had to stand one watch to learn.

VE9SRB <srbest@att.net> wrote:
>I think that we are dealing with two issues here and an application of terms
>in a manner generally accepted by those in the field.

Steve,

To be clear, I'm discussing the IEEE definition of dissipation that
Cecil mentioned, that is the conversion of electrical energy to heat.
Since this is an IEEE definition I assume it is generally accepted
by at least some of those in the field. What I'd like to know is if
the conversion of electrical energy to EM radiation at the transmitting
antenna, and its conversion back to electrical energy at the receiving
antenna, is actually a heat transfer process, since by the IEEE
definition that process would be dissipative. You might have another
definition for "dissipation" in mind, but I'm fixated on the IEEE
definition.

Everything you've said so far is absolutely true, but I also think
that everything you've said so far also precisely describes radiative
heat transfer. By the IEEE definition this process would be dissipation.
I don't think "dissipation" is necessarily bad, if the point of the
exercise is to convert electrical energy to a particular kind of heat
then that dissipation is good. If dissipation is conversion to heat,
however, then it is still dissipation.

>I understand your position that total energy is conserved in one form or
>another. I agree that in the case of the antenna, the thermal or IR energy
>it creates can be detected away from the antenna so it could be considered
>to be "radiated". This "radiation" however is not the form of radiation
>as defined by general antenna theory (gain, radiation patterns, etc).

??? Electromagnetic radiation is electromagnetic radiation. Maxwell's
equations describe how it behaves no matter what its wavelength. I
once wrote a thesis about scattering of light/IR by dielectric and
conducting spheres in a laser beam, and consumed many, many pen plotter
pens drawing the radiation patterns that looked a lot like antenna
radiation patterns (lots of lobes, however, since the spheres were
large compared to the wavelength).

> This
>is considered energy lost or dissipated because it is no longer in the form
>or at the EM frequency of interest.

Here again you define "dissipation" as the radiated energy you aren't
interested in. This may be your definition, but the IEEE definition
is "converted to heat" and the quesition of whether the radiation you

are interested in is also "heat" is still relevant. It is also a question which inherently requires a thermodynamic answer, the IEEE apparently doesn't define "heat".

> One distinction here is the fact that
>to detect this energy you do not use another EM antenna. Thermal heat you >can detect with your skin. IR with the goggles you mention. Radiation of >energy in this form is not the intended function of the antenna. The >antenna's performance characteristics are not described to account for this >radiation (except for the definition of radiation efficiency). The antenna >does not perform in a reciprocal manner (transmit and receive) for this type >of energy.

I don't think it is actually relevant to the thermodynamics whether the apparatus to convert electrical energy into heat, and the apparatus to convert the heat back into electrical energy, is identical or not.

>The real distinction here is that the EM energy radiated by the antenna is >not irreversibly lost through the EM radiation process. The antenna will >detect the EM energy as it passes by. It is functioning as an antenna.

Sorry, "irreversible" is a thermodynamic term and I should have defined it. Because a process is irreversible does not mean that none of the resulting energy can be converted back to the form it was originally in, it just means that it is impossible to convert all of it back into the form it was originally in with no other effects.

Here's an example. Suppose I run a DC current through a resistor. This conversion generates heat with 100% efficiency, the resistor gets hot. I put resistor in a boiler and generate steam with it. I run the steam through a steam turbine, which turns a DC generator, whose output is DC current. Voila, I have now converted electrical energy to heat to electrical energy again.

The reason the conversion to heat is irreversible is not that I can't do the inverse conversion, it is that even if all the components are 100% efficient I can never get the same electrical power out that I put in. In particular, if I need to close the circuit from the steam turbine back to the boiler, I'll need to cool the output of the low pressure end of the turbine. Hence only part of the high temperature heat energy generated by the resistor ends up as DC current again, the remainder ends up as low temperature heat.

The second law of thermodynamics requires this. Conversion of heat to electrical energy decreases entropy. Conversion of high temperature heat to low temperature heat increases entropy. The very best the process can do is to balance these two, such that there is no change to the total entropy. This is called the Carnot cycle efficiency, if I'm remembering correctly.

>The use of terms "dissipation" and "radiation" in this manner is generally >accepted in the industry to account for the distinction in the antenna's >behavior relative to the EM and thermal or IR energy. I don't disagree with

>your discussion of heat and IR. We simply apply the term dissipation
>differently.

But "we" doesn't seem to necessarily include the IEEE, which defines
dissipation as "conversion to heat" whether we like the heat or not.
I'm still fixated on that, and there is a practical consequence to
knowing whether this is a heat transfer process or not regardless.

>Again, the distinction goes back to the antenna's reciprocal ability to
>radiate and then detect the EM energy. Think of the distinction this way.
>Apply an EM voltage to an antenna, EM energy is radiated, it travel to
>another antenna, this antenna detects the EM energy and it develops an EM
>voltage at its terminals. Apply an EM voltage to a resistor, thermal and IR
>energy is created, this thermal and IR energy travel to another resistor,
>does the resistor detect this thermal and IR energy and convert it into an
>EM voltage? This is my distinction between dissipation and radiation.

I don't think the thermodynamics cares whether you can use the same
apparatus at the receiver or not, the issue is the ultimate efficiency
of any receiver you can construct. You are indeed doing a conversion at
the receiving antenna. Electric current moves electrons while EM radiation
doesn't involve any mass, they are different forms of energy. I can buy
solar panels for my roof and directly convert the heat transfered from the
sun, in the form of EM radiation at light wavelengths, into a voltage
at the output terminals, but the power I get will still be ultimately
limited to the Carnot cycle efficiency with the remaining energy
being re-radiated by the panels. The same applies to EM energy
at any wavelength, there will be a limit to the ultimate efficiency
of the receiver with the remainder being wasted by reradiation.

So, here's my bet. I'll bet that the exchange of energy from a
transmitting antenna to a receiving antenna is a heat transfer
like any other. Coherent, because that is convenient for the receiver,
but still fundamentally a heat transfer. Because of this I'll bet
that the operation of transmitting and receiving antennas isn't
reciprocal with respect to efficiency. That is, while it is
theoretically possible to build a transmitting antenna which is
100% efficient (i.e. the conversion to heat), I'll bet it is impossible
for the receiving antenna to convert all the energy it is extracting
from the incoming EM field back into electrical energy at its output
terminals (i.e. the conversion from heat). It will need to reradiate
some of it, and only the remainder will appear at the output. If
you built a sensitive enough detector and aimed it away from the
transmitter and towards the receiving antenna you could possibly
detect the receiving antenna reradiating this energy. No design
would be able to reduce this reradiation below the Carnot cycle
efficiency.

So if the above is true (I still don't know it is for sure, and
I'll admit to not having a clue how to estimate appropriate
temperatures to use to compute the efficiency) then by the
IEEE definition radiation is emitted from an antenna by

dissipation. It may be dissipation that you want to happen, but it is still dissipation by their definition. And this would also mean that, by their definition, radiation resistance is as dissipative as any other kind of resistance, this limiting dissipationless resistance to the transmission line kind. Your mileage may vary.

And, with this, I think I've run well past what I know about the topic.

Not a good analogy. Wal-Mart is engaged in a relatively free market
with lots of competitors. If one doesn't like the price asked by
Wal-Mart, one can go to any number of competitors. If one doesn't
like the price asked by the FCC, what competitor can one go to?
Again, if one is to obtain amateur radio privileges, one is forced
to pay the price set by the FCC which holds a monopoly.

Ok... so it wasn't the BEST analogy, and I didn't say that you shouldn't do things to bring about change. It just seems a real waste of effort to go back and forth about who is right and wrong in the situation. Given time, it will change. Of that, I have no doubt.

Well, you don't need to cool a receiving antenna to pick up rf. I wasn't talking about signal to noise ratio, but the fact that dissipated energy can't be recovered except by expending more energy than that recovered. That makes dissipation irreversible. The process of radiating and then receiving energy is more akin to power transmission, albeit very lossy, than it is to dissipation.

I agree, but there you aren't talking about randomized thermal radiation, which contains no information but its own presence. That would be a power and information transmission system too, with its own inevitable losses and useless dissipation.

From: Delbert McCord <dmccord@usol.com>
Message-ID: <tbivjvrsl2ga12@corp.supernews.com>
Source record: 167829

I had a problem like that 3 months after I had purchased the R8 and installed it. It worked perfect on all bands and them the SWR started climbing the longer the transmitter was keyed down (I use psk a lot). Finally the SWR went to over 8 on all bands. I called Cushcraft and they said it probley was the feedline. I checked the feedline and I thought it was fine but Cushcraft said it HAD to be the feedline. I finally convinced Cushcraft to allow me to send in the matching box. They sent it back to me with a form letter saying it had been checked out and found to be working fine.

A day later I received a message on my answering machine saying the wrong matching box had been sent to me by mistake and they had just shipped me a new one. I installed the new matching unit and it has been working fine every since. (Since Jan 1 2001)

Hope this helps

So what? If you want it, pay the price. If not, don't. There's no other
hobby I know of which provides so many rewards for such a small investment.

Obtain a business license, driver license, hunting license, fishing
license, etc. These are all "monopoly" controlled. If you want one, you pay
the price (and they are a lot costlier than that of a ham ticket).

Yep. Also, it's a damn shame the Department of Transportation holds a monopoly on traffic regulations in this country, 'cause I'd like to switch to one that'll allow me unlimited speed on highways, as well as the right to drive the wrong way in a one-way street while drunk like a skunk.

I made a bodge with a 1/4 wave on the 'active' side of the antenna and a coil on the 'earthy' side- with a bit of a capacity hat at the end (which reduced TVI no end, as it lowered the end volts I guess) for a lashup in my old digs.
Designed it for 7 MHz and it worked fine on that band.
Seem to recall I had a 1/4 wave x .95 (33 feet)- plus 6 foot spare on the earthy side (about 39-40 feet in total). Fed it with some old scrap RG58 and no balun.
I had a near perfect SWR measured at both ends of the feeder cable
As the other reply said- just try and get as much free space wire out there, and load it with inductance and capacity hat/dropping vertical bits of wire.

I am a great believer in spending virtually nothing on antennas, and reaping the enjoyment from a totally home made design- it is the only way to learn properly.
There is a guy local to me (mentioning no names) who has spent over £2000 on HF wire antennas and related test gear over the last four years- and his results never compare (even slightly) to mine.

All you NEED is an SWR bridge, and possibly a noise bridge too (one prefeably that can measure reactance of some sort) and you are in business

Diagram below. The coil was nearly a half wave of wire (66 feet, wound pretty tight, but plastic covered thin wire) and the hat was a vertical piece of wire, about 4 to 6 feet long. BTW: what freq's were you interested in?

And the "price" set by the FCC is not based on any
competitive concerns.

Cheers,
Bill K2UNK

As long as the "price" set by the FCC is rational you'll get no
argument from me. If the state you live in set a driver's license
price of $1000, would you just pay that or would you join the
voice of public discontent and demand rational fees.

Cheers,
Bill K2UNK

Some other comments about reflection come to mind:

Suppose the lossless reflecting surface has certain dimensions. That surface will reflect perfectly. Ignore fringe effect anomalies at the edges of the surface.

Now let the surface become smaller and smaller. The remaining surface continues to reflect in just the same manner. We can pursue this process until the surface is extremely small, almost a single point in effect. Each very tiny segment reflects in the same manner as the larger surface.

The idea is that Maxwell's equations in differential form are "vector point" functions. At each very tiny segment of the surface they operate independently. The behavior over a large

region is the sum (integral) of the behaviors at each of the collection of points.

In other words there is no "sloshing" of electrons back and forth from one end of the reflecting surface to the other. This is identical to the statements about the Faraday shield, where we said that the balance between induced EMF and charge alignment occurs on a point-by-point basis (no sloshing back and forth of electrons between the ends).

The same is true of skin effect. At each location along the entire surface the "skin effect" is occurring independently of other points.

I think this point-by-point process is what is called the "finite element" approach.

I wasn't making a moral judgment, just an observation based on the
way things are. Wal-Mart was not a good analogy to the government.

> Obtain a business license, driver license, hunting license, fishing
> license, etc. These are all "monopoly" controlled. If you want one, you pay

Yep, that's exactly what I said. In return for certain privileges granted,
the government forces citizens to meet certain requirements. That's what
governments do.

I recently installed a G5RV jr (50' long). Desiring a better longwire antenna, started doing a lot of research. Read about such things as SWR, resonance etc.

Then came the questions:

1. how important is it an antenna be resonant if a trans-match makes the transceiver 'think' the antenna is resonant?

2. does an antenna with an SWR of say 1.5:1 perform (get out) better than say an antenna with an SWR of 5:1 but made to look OK with a trans-match?

KE4QJK wrote:
> 1. how important is it an antenna be resonant if a trans-match makes the
> transceiver 'think' the antenna is resonant?

Depends on the losses in the system. Each system component can have
losses. The trick is to minimize the losses to an acceptable level.
Losing half your power is about 1/2 S-unit.

> 2. does an antenna with an SWR of say 1.5:1 perform (get out) better than
> say an antenna with an SWR of 5:1 but made to look OK with a trans-match?

Depends on the kind of coax, the frequency, and the length of coax.
A half-size G5RV has about an SWR of 5:1 on 40m. 100 ft of RG-58 has
a matched line loss of ~1 dB on 40m. According to a chart in The ARRL
Handbook, a 5:1 SWR increases the loss by ~0.8 dB to a total of ~1.8 dB.
The tuner may have a loss of 0.5 dB. Total system losses are below 1/2
S-unit.

The half-size G5RV is designed to be 1.5WL on 10m. It works well on 40m,
20m, and 10m - not well on 15m.

Tom, W8JI wrote:
"How does that "magic" help the user of the antenna hear a signal and through the noise from next door?"

Put next door in the loop`s null.

Loops are shielded because it has been found advantageous to shield them.

Loop response depends on loop balance. The shield helps maintain electrostatic balance.

Radiation from afar has equal E&H fields. Radiation from near sources may not. It depends on the distance from the source. The relative strengths of the E&H reactive fields is a function of distance. The reactive electric field varies as the sixth-power of distance. The reactive magnetic field varies as the fourth power of distance. So, how much of each one depends on distance.

Re-radiating conductors have near fields. Get rid of one of the fields and reduce a contaminating influence on your direction determination or signal measurment.

If you are rotating a direction finding loop, its capacitance to nearby conductors is changing. Electrostatic shielding mitigates this effect.

Why argue against something which has been found to work. There are many cases in which it is not worth the trouble. Nearly every "All-American-5" a-c, d-c radio made for 50 years had a built-in loop antenna. It obviously was not considered important to shield most of those loops. On the other hand, most direction finding sets are equipped with shielded loop antennas.

Best regards, Richard Harrison, KB5WZI

Ah, but the devil is in the details! It helps to know little things like using condensed milk as a cutting lubricant when rethreading the **specific** brass plumbing adapter from 1/8" NPT to 3/8-24 antenna thread. You gotta' get the Don Johnson book. That man has spent **way** too much time in his hardware store, but the details and insights he gives are invaluable.

Yes it is easy to say! Big beams at heights they work real good at are a pain when stuff like this happens! I guess I will climb next week when the wx warms up and look over the X7. I keep checking daily as the wx warms up to see if a change--just a little so far. The X7 is the beam I really care about as I am going to replace the other one with 12/17 beam anyway, but how do you keep water out of the traps to begin with? I made double sure the drain holes were facing down.

Gosh, and all along I kept saying all the shield does is change the balance of the loop.

If an unshielded loop is not properly balanced:

1.) A properly balanced shield will help balance the system.

2.) An improperly balanced shield can make it worse.

If an unshielded loop is properly balanced:

1.) A properly installed shield can never help.

2.) If the shield is improperly installed it can harm balance.

>Radiation from afar has equal E&H fields. Radiation from near sources >may not. It depends on the distance from the source. The relative >strengths of the E&H reactive fields is a function of distance. The >reactive electric field varies as the sixth-power of distance. The >reactive magnetic field varies as the fourth power of distance. So, how >much of each one depends on distance.

So what?

The field impedance is unpredictable of the noise source is unpredictable. The field impedance of the loop does not change one bit, shielded or unshielded. You change nothing, except possibly balance which you might make better, might not, ...or might make worse if you mess up the shield through improper construction or grounding.

>Re-radiating conductors have near fields. Get rid of one of the fields >and reduce a contaminating influence on your direction determination or >signal measurment.

If you "get rid of" one of the time-varying fields, you get rid of all of the time varying fields. The only way to stop the influence of the re-radiating conductor is to remove it, detune it, or cancel its effect through phasing.

>If you are rotating a direction finding loop, its capacitance to nearby >conductors is changing. Electrostatic shielding mitigates this effect.

If the loop is balanced, a surrounding conductor that is not symmetrically placed will ALWAYS unbalance it....shield or not.

>Why argue against something which has been found to work. There are many >cases in which it is not worth the trouble. I'm not arguing that a shield can't help balance of the loop, it can IF it is properly installed. We all know balance is important in a DF antenna. We all know (or should know) the shield does nothing to help S/N ratio....which is all the radio is concerned with.

What is disturbing (frustrating) is how some people think if a "shield" is thrown over a loop it suddenly makes that loop immune to or less dependent on its surroundings. The "shield" has absolutely no effect at all on re-radiation from surroundings.

Somehow people try to extend a simple balance issue into all sorts or arm-waving magic, like the shield makes the influence of surrounding objects magically vanish.

This sounds kind of heave as does using the Diamond antenna and a mount for it. Perhaps a fiberglass safety flag with a J-pole made from 450 window line taped to the flag would work better? I am simply going to install a panel mount BNC connector to the aluminum luggage rack on my bike and mount a rubber duck antenna on it. The added "ground plane" will greatly improve performance over just the duck on the HT, and I have pretty good repeater coverage where I ride anyway. Mind you this can be used on my road or off-road bikes but just moving the rack to the other bike. Since Walt in on a recliner, perhaps he is not as weight conscious as some folks, and maybe a custom mounting bracket attached to the back and top of the seat would work best. It would get the antenna out of the way and up high as well. I saw a site somewhere a couple of years ago that had a ham operating HF on a recumbent bike, as well as APRS and vhf/uhf. I think he towed a trailer too.

The 50 ohm version is known as the "Mini-UHF" connector. It is not
interchangeable with an "F" connector. The outer shell is the same
diameter, so the center pin of the 50 ohm plug must be larger in diameter
and therefore won't fit into the 75 ohm receptacle.

Hi John,

And thus the "radiated power" captured by the antenna must be
amplified by an order of 1,000,000 before that information can be
recovered. By your definition "radiated power" and "dissipated power"
converge.

Saw this posted in the local news, and was wondering if we will be able to see the thing at nite, day, or at all, we live south of San Antonio,Tx.????? thanks for any and all input. news release below.

Russia sets Mir dump for Friday
MOSCOW (AP) - The Russian space agency on Tuesday issued the precise timetable for dumping the Mir,
saying the 15-year-old space station would be brought down into the South Pacific on Friday with a six-hour series of measured engine firings. After Mir descends to an altitude of 132 miles by early Thursday, Mission Control will switch on the station's computer and align Mir for descent. If the sometimes-unreliable computer and its orientation system work as expected, a Progress cargo ship docked at the station will fire its engines twice for about 20 minutes, around 3:30 a.m. Moscow time (7:30 p.m. ET Thursday) and an hour and a half later. Around 8 a.m. Moscow time (midnight Thursday ET), Progress engines will fire again to send the station hurtling into the ocean between Australia and Chile. Most of Mir is expected to burn up in the atmosphere, but up to 27.5 tons of debris are expected to reach the Earth's surface.

It occurs to me that one can test the assertion made here regarding a tubular shield with equipment readily at hand. If the electric field component of a radio signal is the same on the
inside of an open-ended, tubular shield as it is on the outside, then if we place a device sensitive to the electric field component inside such a shield, reception of that signal will be
unaffected.

Try this: Using an antenna short enough to be responsive mainly to electric component of the
incident field, place a receiver and antenna ï¿½ the whole shebang ï¿½ inside a highly conductive
tube long enough to completely enclose the receiver and antenna, tip to base, and perhaps to
extend for some distance past it as well. Leave the ends of the tube open.

If the receiver output remains the same, then the E-field is indeed the same inside a tubular
shield as it is outside. If it is attenuated, then the E-field does NOT wrap around to enter the
tubular shield.

Make the shield is made of a flexible material and you can even bend it into a semicircle, simulating the shape of a loop half-shield up to the gap. But that demonstration is really not
needed. Indeed, the explanation should not be needed; hundreds of these shields are used ï¿½
despite the assertion that the field inside is the same as outside ï¿½ as attenuators, by T-hunters. If the electric field inside a tube were indeed the same as outside, they would not
work.

Referring to the bulk of the energy, true. But the teeny fraction that is recovered is the useful and interesting part.
It occurs to me to look at it from the other direction. If you have a rotating shaft, that carries power from point a to point b, you would say that it was a power transmission system, and that only the losses in the bearings were dissipation. Similarly, if you used a laser beam to carry information and/or energy from point a to point b, it would be a power and/or information transmission system, with some greater losses, but still with some efficiency. The transmission part would be different than the dissipation, which would be lost as randomized molecular motion or the resulting incoherent, randomized ir radiation. Then as you defocus the laser beam and lower its frequency, it becomes a radio antenna (I'm referring to an imaginary transformation, of course). Nothing fundamental has changed in this transformation- only quantitative stuff like the percentage of loss. The information is still recoverable. I think the term dissipation would refer to the randomization of the energy and the information it once carried.
But, then, I'm not a physicist, nor a radio engineer- just an amateur trying to think of a useful distinction. :-)

From: aduffy@sprint.ca
Message-ID: <3ABA43C7.D2978EED@sprint.ca>
Source record: 167869

Does anyone have an idea of the effect of using copper strips instead of the commonly used copper pipe to construct a loop antenna for 80m? ie the effect on bandwidth etc. The 2 strips I have are 4.5" wide (there is also safety edges on them) and 8' long for the main loop. This would basically be just under the equivalent to a 1.5" dia pipe slit and flattened. But you would have 2 radiating surfaces exposed as opposed to 1.

The reason I'm asking so I can modify a nice design I've come across to compensate for the difference if any (smaller circumference etc).

Also would it be better to induction feed the loop using the same flat material (if I'm correct in my assumption on how it works). Or to direct connect as I've seen in other plans (with some form of matching setup).

Also I was wondering if it was necessary to mount the "tuning capacitor" inside the loop or can it be mounted outside without changing any properties of the loop (I don't know if there is any interaction of the capacitor and the antenna or not)

And finally any ideas on controlling the cordless screwdriver to reduce it's rpm without using gear reduction (if possible). I already have an idea to limit rotation to a half rev but don't want the thing to rotate in half a sec or less! :-)

Thanks in advance!

Mark, I have 5 of them 80, 40, 20, 15, and 10 meters. The best way to
tune is to beg-borrow-or steal an MFJ-259 or equivelent antenna
analyzer. Works great. First tune the antenna direct and then run
the 259 through your antenna tuner set to your favorite frequency
and write down the antenna tuner settings for any frequencies you
want to work. Or even make a chart of all frequencies.
It will save you -much- time and frustration. Once you have done all
this you will get great results from the Isotrons. Good luck. 73

We probably all have performed such an experiment by driving through a tunnel while operating a car radio. The tunnel is a waveguide operated well below cutoff frequency in the AM band, and in the FM band the dianeter of the tunnel is much greater than a 1/2-wavelength.

AM signals disappear a short distance into the tunnel. FM signals may go all the way through. This doesn`t seem to me to be a good way to test what a shield does to a loop. I think a shielded/unshielded loop could be easily tested on FM and TV frequencies.

It's the term "electrostatic fields", not "electrostatic capacitance", that was under discussion. The title of section 2.7 of _Radio Engineering_ (Third Edition) is "Shielding of Magnetic and Electrostatic Fields". In it, Terman speaks of "electrostatic shielding", "electrostatic flux", "electrostaic effects", all when speaking solely of time varying fields. I couldn't find anywhere in the section where he speaks of an electric field (which is what I've always called the E part of an EM field). And as Richard has quoted, he plainly states that "It is possible to shield electrostatic flux without simultaneously affecting the magnetic field. . ." I've found that I'm more easily confused than most people, and I do find this a bit confusing. But everyone agrees that Terman is always right, so I'm sure I'll understand it if I continue to study the informed discussion going on here among those of you to whom this is clear.

I realize that your statement that "nobody is confused" is another "literary device", so I won't interpret it literally.

It was on a 70 foot Rohn-25 tower guyed at two levels, 35 feet,
and at 70 feet. The top guys attach to the bottom of the 'hazer'.
The guys at 35 feet are disconnected at the bottom, and brought in
to a 'face' of the tower. When the 'hazer' is rased/lowered, it
'rides down over the bottom guys with plenty of clearance. You
don't want to pick a windy day to raise/lower the thing, but it
worked just fine...

> transceiver 'think' the antenna is resonant?
========================

It is not of the slightest importance. Resonance or non-resonance
of an antenna has nothing to do with its radiating efficiency.

========================

> 2. does an antenna with an SWR of say 1.5:1 perform (get out)
better than
> say an antenna with an SWR of 5:1 but made to look OK with a
trans-match?

========================
No. There's no difference. A transmatch located immediately at
the output of the transmitter has no effect whatever on performance
of the feedline or antenna. The transmatch merely adjusts the load
presented to the transmitter to some desired value such as 50 ohms.

Hi David--

My guess is 250 feet of wire should resonate around 75 meters (not 160) when coiled in this fashion--and make for a really lossy antenna.

Take a close look at what your restrictions are and what you can do to get around them.

For example, better to zip a lawn edger across the yard in the middle of the night when nobody's looking and bury 200-300 of coax leading into the forest than to put up a lossy antenna near (or in) the building where it can interfere with everyone's consumer electronic toys. Then you can put up a real multiband antenna (like a G5RV) and not bother anyone. You may lose 3-4 dB in the long feedline, but that loss will do wonders for flattening out the antenna's SWR--and you'll get out just fine.

Well.....
I recall the Gotham vertical. Actually, it wasn't too bad an antenna. Just from memory, I believe it was about 20 feet tall, with a coil to ground at the base. The feedline tapped the coil near the bottom, and the vertical radiator tapped the coil at various points for various bands. The last one I remember seeing used a coke bottle as the bottom insulator!

How does a short piece of copper or aluminum tubing differ in operation from
the tunnel?

That would not be the retina (not that the retina is not damaged too!).
Perhaps the conjunctiva, cornea, or sclera.
The retina is the internal surface in the back of the eyeball.

5560. Push up Mast

Refering to the bulk of power is necessary and inescapeable.

Incoherence does not follow as a necessary component of the situation.
This is not a product of information loss unless you absolutely
require the same frequency out as applied. But then almost no
commercial receiver detects baseband signals, they convert to one or
more intermediate frequencies.

>Then as you defocus the

>trying to think of a useful distinction. :-)
>
>john

Hi John,

The expectation that the IR must exhibit coherence to NOT become dissipative is an extraordinary addition to the "definition" of dissipationlessness. However, aside from red-shifted responses, the modulated data is still all there. It is simply suppressed by the low pass filter of the thermal mass. This is indistinguishable from path loss for which receivers are already designed to accomodate. (I will admit we are now talking about two different receivers, but the physics is the same.)

As this and threads like this grow, so do the qualifiers appended to the "definition" to fit the problem to the answer. such a growing definition begs the question: why so much explanation to replace the simple observation that "the power never returns" which is sufficent, and unambiguous.

The IR argument is not one of utility, it simply offers a disjoint to the IEEE mandate and exposes the inherent weakness of their definition.

Go to the TV antenna section of Lowe's, Home Depot, or Radio Shack
and look at one.

Message-ID: <3ABA84AE.21B2B639@eznec.com>
Source record: 167886

I agree with Richard. We have to be careful with our comparisons. A waveguide is a different critter than a coaxial cable. There's no way you can get, say, 10 MHz energy to go much more than a very small distance into a half inch diameter waveguide without tremendous attenuation. The tunnel behaves this way at AM, as Richard says. But put another conductor down the middle of it, and a different mode, or field distribution (TEM) is possible. So there's no problem getting 10 MHz down a half inch piece of coax. Go down the half inch waveguide a few inches and you won't be able to detect any 10 MHz energy, but there's plenty at any point inside the coax (except inside the conductors of course).

Cortland Richardson wrote:
"How does a short piece of copper or aluminum tubing differ from a tunnel?"

Size and scale. Tunnel or tube can be conducting material and mode tubes.

A conducting tube must be at least 1/2-wavelength in one transverse dimension to support radio propagation unless the tube has another conductor such as coax has to support propagation at frequencies lower than the 1/2-wave cutoff frequency.

I was considering the whip antenna as a capacitive probe as it is short in terms of frequency.

Best regards, Richard Harrison, KB5WZI

Try it.

Try to receive a signal with a ferrite rod antenna inside the tubular
shield (with no lengthwise slot in the shield). Tell me how well it
receives.

After all, you are saying the magnetic foeld will pass freely through
the metal shield.

Take your transitor radio, and place in the middle of a hunk of stove
pipe a few feet long open on each end.

I'm puzzled by something.

If Terman is always right, and we can accept every word his says
literally, why did his books change from revision to revision?

Did someone else sign his name on the earlier editions? Could it be
that some concepts are difficult to explain in a few words?

Hi roy,

There is a real correlative to this found in the traffic tunnel north
of the Golden Gate Bridge (on the way to Sausalito/Tiburon).

To allow drivers to hear their favorite AM broadcasts without losing
the feed during their time in the tunnel, the bridge engineers strung
up a wire that ran outside of the tunnel and then fed into it. That
is, they forced the signal into the interior by creating an offset
coaxial transmission line wherein the cars were always within a field.

Yes, at AMBC wavelengths a tunnel works the same as a conducting tube, or close to it, anyway. However, the probe orientation for a car going into one is normally perpendicular to the axis of the tunnel (we hope) whereas the the probe orientation for a radio and whip inserted into a tubular shield would be normal to the axis of the tube.

Denver Braughler wrote:
"That would not be the retina (not that the retina is not damaged too!). Perhaps the conjunctiva, cornea, or sclera."

I suppose the nerves in the retina are specialized in sensitivity to light and may disregard other stimuli. As I said before, working in a shipyard produced almost chronic itchy, scratchy, sandy eyes for me and we knew the cause. It wasn`t severe enough to be disabling and we knew the cause but had no treatment. The welders had their masks, but we weren`t much on precautions then. Chipping hammers at work right along side, but no ear plugs. Insulators installing asbestos, but without masks, etc. The only antidote we had plenty of was the salt tablet dispenser. Those were everywhere to replace salt lost in the gallons of sweat we all produced.

If you needed something, the ready answer was: "There`s a war on, you know." I soon volunteered for the navy.

Best regards, Richard Harrison, KB5WZI

I really wanted to stay out this but ole weird Roger is in so many newsgroups and he is the type of guy that everyone would love (to put duct tape over his mouth). But I find myself wanting to show him what I was told about libel laws.

Libel is proven in a court of law when the words, spoken, uttered, written, and or published which caused the libeled to be embarrassed to the point of duress. Do you think Roger has reached that point?

Some one near Roger's city should try to find out if Roger, cross dressing as a person, and the gall of imitating as an Amateur Radio Operator, has a job. (I doubt it.)

Someone should find out if the EM99 in his signature is related to Emergency Management or the local police identifier number for one weird mental impaired first class nut.

Why. Because if someone could find this information out I am sure the employer would not keep him around and certainly not the Emergency Management Agency of "it's" county!

Times getting short Roger. Repent your wicked ways my son. The end is coming sooner then you think. (my son! If you were my son you would not be on the internet you would be sitting in the hospital recovering from having fallen into the computer monitor.)

Now you have ME confused- is there a difference between "perpendicular
to the axis" and "normal to the axis" ?

We may have found a part of your problem.

Hi to all,

I'm looking to get a HF antenna and found the MQ-1 antenna details
at www3.sympatico.ca/tgmc

Has anyone work with this antenna or any antennas from this company
? Any comments welcome.

Thanks in advance

Tom, W8JI wrote:
"Could it be that some concepts are difficult to explain in a few words?'

Yes, and some are even more difficult to explain with many words.

My first copy of Terman is the 1937 edition which updated his 1932 publication. I bought it used in 1947 at the university bookstore. The price marked is $4.75, not cheap for a used book then, but worth every cent. The 1955 edition of Terman is many more pages, but still remarkably free of errata.

Think how much growth of information transpired in the years between `32 and `55. Electronics progressed from new indirectly heated cathodes to transistors in that 23 years. Television went from a laboratory curiosity to a huge industry that captured the attention of many individuals for hours every day.

Many more pages were needed in 1955 just to barely cover the field.

Best regards, Richard Harrison, KB5WZI

5581. Re: Push up Mast

Newsgroup: rec.radio.amateur.antenna

Source record: 167904

The common push up mast is several pipes about 10 feet long each. They are made to telescope inside each other . while this is only an example and would be looser than the push up mast, picture 3 pieces of pipe. One 1 inch in diameter, one 2 inches and one 3 inches in diameter. You put them together and push up one pipe, it is made so it will stop and not come out the top and there is a pin you put in to keep it from comming back down. Then you push up the next pipe and pin it. Yo now have a 30 foot mast. When guy wires are used they will hold small beams and rotators. You can get them form aobut 20 feet to 50 feet tall.

Courtland Richmond wropte:
"However, the probe orientation for a car going into one (a tunnel) is normally perpendicular to the axis of the tunnel---."

Yes, and that is completely normal for probes in waveguide and coax. Take the coax slotted (trough) line probe for example , or a waveguide 1/4-wave feedhorn radiator as used with some parabolas. These are perpendicular to the axis of the coax or waveguide, too.

Best regards, Richard Harrison, KB5WZI

I had the original HQ-1 Mini-Quad made back in the 70's and early 80's, and provide the following info:

20 meters - totally worthless (rotation has no effect on signal strength)
15 meters - practically worthless
10 meters - fair
6 meters - decent

Spikes frequently break off
ceramic coil forms sometimes crack
I melted the potting compound off the coils with 500 watts PEP!

Other than that, it's a pretty good antenna!

But these people would argue that the "price" set by the FCC (the code testing requirement) is not rational - it is not rational to still maintain testing for morse code when all other radio services have long ago dropped a similar requirement, or when code has been virtually eliminated in all other radio communitions (commercial, military, governement, marine, and so forth).

The code test requirement once served a purpose - to provide a means of code education for those who might enter other radio services and to provide a pool of trained operators to serve as a backup for other radio services during emergencies. Those purposes no longer exist today - the other radio services don't need people educated in code and CW is a very poor backup for cellular telephones, satellites, and electronic mail.

Source record: 167907

I am going to set up a sloper 160 meter antenna using my 55ft tower,
alpha delta center insulator and 122 ft of radio works flexweave wire.

The catch is at about 85 ft I must make a 45 degree band for the
remaining length.

A friend suggested folding back the wire.

Any suggestions?

Ps, reason for the bend, property line limitation.

TIA..

Hello Bruno,name is Dennis VK4SX,Bruno last year i became ill, and was
concerned about my antenna arrays,so i took the plunge and removed my 6 band
6 element beam and replaced it with the TGM MQ-2 , the 6 mtr section
of the MQ-2 isn't being used as i have a 5el yagi,but as far as
20/17/15/12/10 mtrs goes,works very well is quite well made,easy to tune,or
course the trade off is bandwidth on 20 mtrs ??(abt 175khz under 2.1.1)has
respectable front to back,and shows some gain,catche's less wind than some
verticles weathers storms extremely well,i live on the east coast of
Queensland and my concern with my other antennas was if it all fell down
when i wasn't home,hence the TGM MQ-2..if you decide to utilize the 50mhz
section talk to Tom Mackay and see what balun he settled on to cover 14mhz
thru 50mhz ?? as most baluns fail above 30mhz.
ok hope this helps.
Kind Regards
Dennis
ps
pass my rgds to Tom

I think I have come up with an answer. I went to the local hardware
and found some 3/8" fiber glass rod, which is the same diameter as the
aluminum rod supporting the fabric on my bike. I think when I replace
the present rod with this I won't have the reflection problems I was
concerned with. I will try to get it completed this weekend and I will
report back.

Thanks to all for the constructive help. (Even though I still won't
use a bike flag ;-))

5589. Re: Antene ATV

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-23 04:41:45 UTC
From: richardharrison@webtv.net
Message-ID: <9397-3ABAD409-239@storefull-114.iap.bryant.webtv.net>
Source record: 167914

Luis, CT2HKY wrote:
"Please send me the scheme of a 23cm antenna for ATV."

The easiest high-gain (14dbd) antenna is probably the rhombic.

At 1.3 GHz you need a line-of-sight path. 30km is 18 miles, and line-of-sight depends on altitudes of the antennas at both terminals, and any obstacles in the path.

Arnold B. Bailey wrote an excellent book, "TV and Other Receiving Antennas". Reciprocity rules, so the designs can be adapted to emission as well as reception. Bailey includes a TV rhombic designed for 200 MHz. To scale it for 1.4 GHz, we shrink it by a factor of 6.5.

The shrunken rhombic is (4) straight conductors forming a diamond. The rhombic is formed from (2) wires. Each wire is 170 cm long. These wires are separated by 85 cm at the middle.

One end of the rhombic will be directed at the repeater Luis wants to use. Connect the wires aimed at the target together through a non-inductive resistor of about 600 ohms. It should be capable of dissipating about 1/2 of the power of the transmitter used.

At the radio end of the rhombic, the drivepoint impedance is also about 600 ohms. depending on the wire size used in the rhombic a 600-ohm wire spacing may be about 30 cm. An insulator may be used to get this drivepoint spacing. A tapered line may be used to reduce the impedance to a lower value. If this can be placed in the same plane as the rhombic, line radiation may add to the antenna gain. 2-wavelengths (46 cm) is a good length for a tapered line. This is not critical. It could be 2x this length or 1/2 this length and work well. The tapered line can cut the impedance to 150 to 300 ohms by making the spacing the same as those on your line connector (about as close as you can get the wires together without shorting them). The impedance may actually be lower than 150 ohms.

A 1/4-wave matching line section can also be used to lower the line impedance, or a more exact exponential tapered line section can be worked out, but the simple approximate approach will probably be fine.

An Australian tried a similar rhombic and tapered line matching section a few weeks ago and reported excellent results.

Best regards, Richard Harrison, KB5WZI

Amateur radio covers a wide spectrum of methods and modes. Some people specialize in SSB, others AM, still others TV, low power, EME, and yes some CW.

Qualification for an amateur radio license covers that same spectrum. We are tested on the Rules and Regulations governing the service. We are tested on our understanding of proper and appropriate operating technique. We are tested on how a radio signal is generated and detected. We are also tested on modes of operation i.e. ssb, am sstv, atv, antenna design and operation. And. We are tested on our comprehension of digital modes of communication to include morse code. To say that we should not be tested on a segment of the service just because it is old, outmoded and not used for anything ignores the fact that code is part of our general knowledge and an important part of our heritage.
I, personally, have a tin ear with some hearing damage due to loud noise encountered during my working career. I passed the 5 wpm code test for Novice/Tech Plus Plus many years ago. As a novice I made a number of CW contacts poorly. I upgraded to Tech and remained such until last year when I was able to upgrade to Extra. No I am not a fully qualified Extra as defined by some but I did work to learn that which was required by the FCC to qualify for the license. I also learned more than that which is required. This is the price I paid for my chosen hobby. I have also used my knowledge so gained over the years as a communicator in Civil Defense, Civil Air Patrol, various places of employment for a total of atleast seven radio services. All of this because I took the time and effort to learn the code. I have not, to date, used my morse code knowledge for anything other than to take the test but I am glad that I do know it.

Let me say in closing that the comments of Dwight Stewart, while contrary to what I believe, are just a valid as mine and, who knows, may be right. I have noticed some comments in this thread that are mean spirited and meant to agitate not convey rational argument. So, by all means lets continue the dialogue but lets keep it civil.

Well, at least you passed the test, which adds a lot of validity to your opinion, pro or con CW. I personally find it hard to validate the opinions of those who condemn what they have never achieved.

In a trial, there is a thing called an expert witness. This person is allowed to enter their personal opinion on a subject as evidence because of their experience and expertise in the field of questioning. However, a common layman's personal opinion is disallowed due to lack of expertise on the subject.

Amen. It is obsolete, totally irrational, and part of the very definition
of an Amateur in the treaty and will be for the next five years or so.
Anything over 12 always was ridiculous.

Given that, what are you going to do about it? You could pass it, you
could simply shut up and wait, you could send out for a pastrami on white

with mayo, have sex, or expect rain. There are any number of wondrous things to be accomplished.

So for why are we treated to the self-serving observations on the obvious? Why not try to sell someone who matters? We are just a bunch of people who cared enough to DO it and know bullshit when we see it. I don't care if you pass it or not but please do not insult my intelligence.

The incoherence is part of the randomness, or the lack of signal. After dissipation, there is nothing but some fuzzy warmth, and then only to colder objects. There is no necessity of sameness of frequency, but when you convert a single frequency or a limited set of frequencies carrying information into

heat, then you have a random mix of frequencies without information.

The IR really has nothing to do with it- heat at a certain temperature level is in the IR range. Heat at a much lower temperature would be random, incoherent RF. But there is a difference between heat and signal. It seems peculiar to say that the modulated information is still there. To the degree that you look at it as a low pass filter, and to the degree that the signal does get through, it is not dissipated. The signal that doesn't make it through the filter, and is dissipated, no longer exists as signal.

Tom, W8JI wrote:
"We all know (or should know) the shield does nothing to help S/N ratio....which is all the radio is concerned with."

Another "expert" to weigh in on the side of the shielded loop is W.N. Christiansen, contributor of the "Aerials and Transmission Lines" section of F. Langford-Smith`s Radiotron Designer`s Handbook".

He says: "The reason for this is that a balanced or shielded loop responds to the magnetic component of the field of an aerial, whereas the capacitance type aerial responds to the electric component. In the radiation field they (E&H fields) are equal and mutually dependent. In the immediate vicinity of an aerial they are not equal, and the electric cxomponent increases more rapidly than does the magnetic field (component) as one approaches the aerial. Hence in the vicinity of a radiation source of r-f noise, a loop aerial will pick up less (noise) energy than will a vertical aerial."

OK. In the near field, which depends on the size of the aerial (noise radiator of opportunity), the electric component from a noise source is larger than the magnetic component. So, in the near field of a noise source, an antenna which is more responsive to the magnetic field than it is to the electric field will have a S/N advantage over an antenna which responds equally to both components of the near field. This has more to do with the size of the noise radiator than it does with the size of the loop (so much for a distance of "a couple of loop diameters").

We have a whole pantheon of "experts" contradicting Tom`s declaration that the electric field is "inseparable" from the magnetic field by the shield around a loop antenna. It is just an example of a Faraday screen or electrostatic shield. I believe Terman started with the electrostatic shield in an ordinary transformer as his first example. Adding another to the gallery of dead "experts" is unlikely to change Tom`s mind. Thanks anyway, Mr. Christiansen.

In that case consider the X-Ray tube at 2% efficiency if you're lucky.

What was that about from DC to blue light?

Obviously you haven't done any Radio Astronomy where to the average listener
the signals are indistinguishable from noise.
In fact a great deal of information is carried by that noise if you know how
to extract it.

Think of a simple example of noise carrying information.
The thermostat on next-door's water heater,
Brrrp! they're having a shower again.

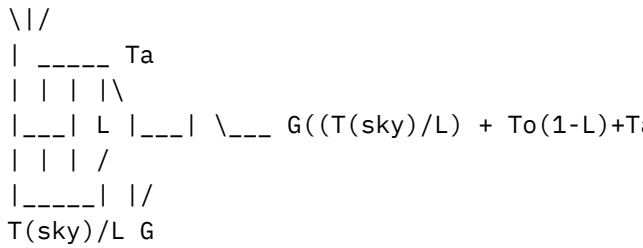
"Ian White, G3SEK"
I guess we have come some way off topic, and now that some time has passed for the original topic to digest I was a little disappointed that no-one came up with this simple solution (View in fixed font)

T(sky)



Where T(sky) is large compared to To and G approximates L
And Ta is equal to or less than To
Noise delivered to the output terminal of the antenna plus amplifier approximates T(sky) + To
Signal out is S G/L
Signal to noise degradation is T(sky)/[T(sky)+To]
or 10log(1+[To/T(sky)])

If G is much larger than L the antenna inefficiency loss then degradation of signal to noise does occur. I guess having a preset gain control on the amplifier to set it about equal to or very slightly greater than L will help.
This only works because T(sky) is very much larger than To

Obviously many Hams are quite afraid of a little simple maths;
shame really cos they are missing out on a most pleasurable part of the hobby.

As for exercising ideas, they are intended as thought provokers for those not as expert as the old hands that like to think that they are; sort of one stage further than RAE revisited.
The bit of kit that you designed and built yourself has infinitely more pleasure than the expensive factory made one.

Tom, W8JI wrote:
"Gosh, and all along I kept saying all the shield does is change the balance of the loop."

Well, there`s more to it than that. The shield can help keep the balance of the loop from changing. It also has another function, that is to make the loop insensitive to the electric field. A host of distinguished authors say so.

Terman, on page 38, "Electronic and Radio Engineering", 1955, says:
"It is possible to shield electrostatic (yes this means time-varying electric lines of force) flux without simultaneously affecting the magnetic field by surrounding the space to be shielded with a conducting cage that is made in such a way as to provide no low-resistance path for the flow of eddy currents, while at the same time offering a metallic terminal upon which electrostatic flux lines can termnate."

The insulated gap in a loop shield breaks the path for eddy currents (those pesky currents which go in circles, in this case it would be all the way around the shield loop were it not for the insulated gap in the shield). But, the insulated gap loop shield does offer a terminal for the electrostatic limes of force (and a terminal is an end, in this case for electrostatic lines of force).

So, we have a shielded loop which is responsive to the magnetic field but unresponsive to an electric field.

Tom can deny all he wants, but many authors say the same thing and some gave papers to the IRE on the subject about 70 years ago and these data have not been refuted and are references which later authors give for their work.

Marvin, N3BQA wrote:
"Would it be pratical to use an r-f ammeter before and after a
transmatch instead of an SWR meter?"

An ammeter can determine SWR if measurements are taken at points
sepatated by 1/4-wavelength on the line to get the ratio of maximum to
minimum current.

To get power at a point with an ammeter you have to know the impedance.
If you know the power and the impedance you can calculate the voltage,
and so it goes.

What anyone really needs is a Bird wattmeter.

5605. Homebrew Coax Colinear Tuning - Help Please

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-23 10:47:18 UTC
From: Nick Filer <nick@cs.man.ac.uk>
Message-ID: <99f9h4$sc3$1@m1.cs.man.ac.uk>
Source record: 167779

Last night I put together a coax (RG58) collinear for 435MHz. The design is 8 half waves connected as usual centre to braid, braid to centre (see diagram). On top I have a 1/4 wave of wire connected to the centre core. At the bottom I have a 1/4 wave of aluminium tube. The coax was cut into 235 mm lengths. Each length has as close I could measure/check it 4mm core, then 3-4 mm braid exposed at each end. This should give a transmission line of 227-228 mm, or conversely a 1/2 wave at 435Mhz or thereabouts. To keep it straight it is all attached to a long doweling rod.

Key: === - coax braid --------- - coax core +++++ top 1/4 wave

```
_________
========||======-----------======-----------======-----------========-
--------------++++
----------------||-----------======-----------======-----------=======--
-------------========
---------------- 1 2 3 4 5
6 7 8
^ ^
Feed inside 1/4 wave
Al tubing. Tight fit!
```

With the feed core connected to the lowest 1/2 wave's core and the braid to the braid I got an SWR of 3. The centre seems to be around 435MHz where I wanted it. It rises a bit at the edges of the UK's 70cm band which is 430-440MHz. I managed to pull the SWR down to 2.5 by adding a ferrite bead to the feed about 1 wavelength below the aluminium tube. Moving the tube up down a bit seems to have no effect on the SWR at all. I tried trimming the top 1/4 wave but this had no noticeable effect.

Any ideas how I go about tuning this thing. I have an SWR/power meter for the band and an analogue VOM?

My thoughts:

1. Would it be better to attach the antenna feed to the braid of the lowest element. That way the top 1/4 wave would be attached to the main feed.

1a. If so, would I connect the aluminium tube to the antenna feed or to the ground feed?

2. Given that RG58 braid is very fine and therefore my transmission lines are probably not very accurate +/- 1-2 mm in places. Would it be a good idea to find some way of ensuring the braid at each connection is the correct length. My initial idea is to cut a thin strip of aluminium cooking foil and wind it around the exposed braid at each connection. An alternative might be fine copper wire of any type wound around and perhaps soldered.

Any help/advice would be gratefully received.

Nick - M1NIC

The other obvious thing, is to make sure you use your space
efficiently....like sloping at an angle and going diagonally accross you
yard/garden whatever.
It is amazing how much more wire goes up in the air with a careful bit of
thinking.

That's a pretty good explanation. The only amendment I'd suggest is that T(sky) is not appropriate on the lower bands where antennas don't have much directivity - well, not much by UHF, microwave and radio astronomy standards - and will pick up noise from all directions. T(ambient) might be a better label.

For an in-depth tutorial on noise and practical noise figure measurements, try:
http://literature.agilent.com/litweb/pdf/5952-3706E.pdf

I'm all for that (and have some track record in that area) but also I
strongly believe that, in amateur radio and much else, theory needs to
be tied to an awareness of the practical knowledge that already exists.
The real power comes from theory and practice working together.

>The bit of kit that you designed and built yourself has infinitely more

That is utter nonsense Richard.

The field impedance of the loop with a shield is EXACTLY the same as the field impedance of a loop without a shield.

Anyone who knows anything at all about EM waves should understand that.

>Terman, on page 38, "Electronic and Radio Engineering", 1955, says: >"It is possible to shield electrostatic (yes this means time-varying >electric lines of force) flux without simultaneously affecting the >magnetic field by surrounding the space to be shielded with a conducting >cage that is made in such a way as to provide no low-resistance path for >the flow of eddy currents, while at the same time offering a metallic >terminal upon which electrostatic flux lines can termnate."

You lifted that text out of context. Terman is talking about shielding common mode coupling in things like transformers and coils , not antennas.

There is a vast difference between these two situtaions because of the MODE of coupling.

Your mistake is in trying to apply common mode shielding, such as between two resonant coils inside an IF transformer, to a large loop antenna receiving a signal from several loop diameters away.

Clearly you have a mindset that somehow the time-varying electric and magnetic fields are independent. With such a mindset, the CFA antenna is a practical antenna. That incorrect view is at the root of all kinds of antenna nonsense.

>So, we have a shielded loop which is responsive to the magnetic field >but unresponsive to an electric field.

In your dreams.

1/10 of a wavelength from that loop, in open space, the reponse will become electric field dominant. Want to bet on it?

Hundreds of lines of math, all correctly done but using wrong
assumptions, is worthless. It impresses no one, except perhaps the
writer who becomes self-enamored with himself.

It may be fun to add and subtract all day, but to be useful in solving
problems it is critical we know what data to use and how to use it.

>As for exercising ideas, they(1) are intended as thought provokers for those(1)

>the bottom I have a 1/4 wave of aluminium tube. The coax was cut into 235 mm

Hi Nick,

This antenna requires the INSIDE of the cable have about the same
velocity factor as the OUTSIDE of the cable, or it will not work.

If you built the coaxial collinear out of RG-58 it will not work. Wad
it up and throw it away. or enclose it in something that makes the
wave on the outside of the cable travel the same speed as the wave
inside the cable.

This design was stolen from the Stationmaster antennas by
Phelps-Dodge.

In early model Phelps-Dodge antennas, the antenna was surrounded by a
thick layer of wax (about 1" thick). The size of the conductors was
chozen for the correct impedance, and the wax made the velocity of the
wave outside the cable the same as the velocity inside the cable.

In later ones, they went to an air-dielectric transmission line
suspended in an air gap between a thin fiberglass radome and the
cable. There was no dielectric outside the cable.

You can not sucessfully duplicate this antenna using regular RG style
cables hanging in air. Even if you get the SWR right, you'd have more
gain from a 1/4 wl groundplane.

I would say, as a matter of definition, that signal is not noise, and the radio astronomers probably go to great lengths to differentiate the two. If they didn't, they'd be listening to their own ears.

45 degree angle is much better than a 90 at the property line. Slip a
couple of "floating" insulators on the antenna wire before connecting your
end insulator. "Snake" the wire to the property line by first bending it to
left then right, or whatever direction you need to go, ending up with a
couple of mellower bends, say 20 and 25 degrees, in sort of a stretched out
Z shape. Might not skew the signal as much as one harsh bend.

All true, but you don't consider that none of the other modes
are tested on a separate pass/fail basis as code is today.
I have no problem with adding some test questions to the
overall test/knowledge syllabus on code as a mode. There
is,however, no longer need to test anyone's individual
code ability as a stand-alone skill test on sending/receiving.
That's no different than not testing on ability to type
using a keyboard for packet or RTTY.

>I, personally, have a tin ear with some hearing damage due to loud noise

You are an excellent example of why there is no longer any
need to mandate code skill testing. If and when you ever decide
to use code, you will be relearning much of the skill and ability.

Yesterday I noticed some increased noise on receive while cruising 70mph on the freeway (no toll roads in MI). When I exited and started slowing, the noise started to decrease. When I got down to about 30 or 40 mph it was gone. I shifted to neutral and rev'd the engine, but no noise (other than normal) so I figure it was the tires. The ham I was talking to said to put some graphite powder on the sidewalls. I never heard of this.

Do tires, steel belted radials in particular, create interference?

Is there any truth to the graphite idea?

Can tire static if that is what it is be effectively eliminated?

Thanks to all for the constructive help. (Even though I still won't
use a bike flag ;-))
Walt Smith

Walt--you should fly a little "pirate flag" flag on the top of your antenna!
The fiberglass rod sounds like a good solution, however, why not just mount
the antenna to the aluminum tubing thereby incorporating the aluminum, which
I assume is mechanically attached to the frame, into the ground plane scheme
of things. The more metal you have under this antenna the better it will
work!

If you can get the supports into the trees high enough, you can possibly make do with only 50 feet, providing there is enough room past the trees to pull the extra wire tight.

This antenna generally has a 34 foot twinlead feeder. Like any other antenna get the feedpoint as high as possible, and try to arrange the feeder at a 90 degree angle with respect to the wire.

Center the feedpoint between your supports. You can then pull the "extra" wire past the trees and angle them down toward the ground. Anchoring the wire ends is now the problem. Fence posts can be used or ground anchors, other smaller trees, etc. The important thing is safety, keep the wire ends out of reach. Use good end insulators for attaching the guy(ceramic is best for this) to the support.

If the space is really limited to the 50 feet, you can also run the wire straight down the side of the tree (but not touching the tree). If your tree support is high enough....

Neither approach is ideal but you are going to need a tuner anyway. It beats no antenna, and should work better than a light bulb.....

5630. Re: Homebrew Coax Colinear Tuning - Help Please

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-23 16:11:51 UTC
From: Nick Filer <nick@cs.man.ac.uk>
Message-ID: <99fsho$d5o$1@m1.cs.man.ac.uk>
Source record: 167804

Thanks Tom,

I did wonder a little at the velocity factor difference between the outer and inner. Would putting inside a PVC tube help? This will lower the external VF to about 0.8 (I think). If velocity factor is non cumulative then this should reduce the SWR? Is there a type of tubing with a lower velocity factor? Presumably if the tubing has a VF of 0.66 then the antenna should work - even if the losses are high? I have a table somewhere that suggests that Polyethylene has a VF about the same as coax - it is often used as the dielectric. Perhaps this would be the ideal material for this particular antenna. I will try and improve it and then send it to the scrap heap if it is still weaker than my 2 meter J-Pole used on 70cm's.

The naive advantage I saw in a coax collinear was that it is cheap, straight, for 70cm's relatively short and supposed to be easy to match. My next attempt will probably be one of the many ladder-line designs though these require some matching.

Nick

My first guess is you don't want either antenna! All antennas achieve their power gain by redirecting radiation from one area to another. So in the case of a high gain antenna most of the RF will be radiated in a flat horizontal plane around the antenna. With a pattern like that you may find that other stations, and even repeaters, will be in an area of greatly reduced RF radiation, i.e. low signal strength, resulting in poor performance. A quarter wave ground plane, cheaper too, has a wider radiation pattern, which gives better coverage for your case. High gain vertical antennas are more useful when working out in open country, and the terrain is relativity flat.

I would imagine it would be standing waves. The few RF ammeters I have seen use a thermocouple element to sense the AC current. I can't see how an instrument like that can distinguish between a forward and reverse traveling wave of current.

The same can be said about pregnancy and child birth. If you can't get
pregnant, or give birth to a kid then I guess that person's views on
abortion are not valid either, right?

The argument that if you don't know CW you can't have a valid opinion about
it is crap. I'm sure you can't get pregnant, but I'll bet you still have a
valid opinion about abortion none the less, which is the same argument about
CW, but in a different context.

For what its worth, MARC, the motorcycle amateur radio club did extensive antenna testing on 2M-440 for use on motorcycles. That's kind of worst case as a motorcycle provides very little ground plane as compared to an automobile. The top performing antenna for everyday use was the Comet HP32. If you wanted the absolute last foot of reach in a fringe area, the Comet Z780 was the one to have. Both outperformed the Diamonds.

Just picked up a Sinclair Duplexer, Model R-312CR
that appears to be a "reject" type of setup. Four cans and tunable rods in
the middle. I wanted to use this for a low
power repeater in our area and the tech who sold it to me said it would be
good for up to 50 watts but it really kills the sensitivity of the receiver.
Has anyone had any experience with these duplexers? Any pros or cons?

I am looking for any information pertaining to this duplexer. Thanks!

Anyone replying to me rather than the newsgroup should
remove NADASPAM from the email address.

Cecil, W6RCA wrote:
"Does an RF ammeter measure traveling waves or standing waves?"

An RF ammeter measures the combined currents, forward and reflected, at the point of the ammeter`s insertion in the transmission line.

An RF voltmeter measures the combined voltages, forward and reflected at the point of the RF voltmeter`s attachment across the transmission line.

At a current minimum point on the transmission line, (voltage maximum point), the impedance of the line is resistive.

At a current maximum point on the transmission line, (voltage minimum point), the impedance of the line is resistive.

At a current minimum point on the transmission line the value of the resistance of the line is:
SWR x Zo.

At a current maximum point on the transmission line the value of the resistance of the line is:
SWR / Zo.

So, with a slotted line, some basic instruments and some calculations you can tell what`s going on with your transmission line. I still prefer my Bird wattmeter.

Best regards, Richard Harrison, KB5WZI

I agree that to some "T(sky)" might be the subject of some discussion,
but from my 5' 6" up is up.
I don't like the idea of T(ambient) because it is too readily confused with
To
which especially in the IEEE definitions of noise figure has the specific
value of 290°K despite the fact that Rules and things are calibrated at 20°C
or 25°C = 293°K and 298°K respectively.
The nice round number 300 makes illustrative calculations a little easier
too.

> strongly believe that, in amateur radio and much else, theory needs to
> be tied to an awareness of the practical knowledge that already exists.

I must agree with that as I started my Radio life as an empiracist of 14 and
remain such until 19 when I started to learn better. I think that since
becoming more theorist I enjoy Ham Radio MORE, and commend the hard work to
one and all.

Hi Dennis:

Rather than interjecting my comments throughout your discussion above, I thought it would be easier to do it here.

As you state above, EM radiation is EM radiation. Some of my comments regarding antennas were simply written to point out that we define the antenna's radiation properties in terms of how it radiates the EM energy delivered to its terminals.

My discussion of dissipation was somewhat ambiguous because of the separation of thermal and IR energy. In this context, my definition of dissipation was considered to include thermal energy and the radiated EM

energy of no interest (IR). You point out that the IEEE defines dissipation as the conversion of energy to heat. Both definitions are essentially the same and understanding heat is the issue.

The issue is energy conversion, transfer and detection. I think we all understand what happens to the EM energy delivered to the antenna. A portion of the EM energy is radiated. The EM energy not radiated is converted to another form and is considered to be dissipated as heat. We account for this energy dissipation in defining the antenna's radiation efficiency. In discussion the resulting IR radiation that occurs with the energy conversion, we are now really discussing a heat transfer process. The energy dissipated in the antenna (heat), or resistor if you prefer, can be transferred in several ways - convective, conductive, Ebuillient and radiative. IR is simply the process by which long-wave electromagnetic radiation transports heat from a surface to its surroundings.

Hi Richard:

Provincial? I don't quite understand.

My choice of wording might have been poor. The point that I was trying to make is that we define the antenna's radiation properties in terms of how it radiates the EM energy delivered to its terminals.

Well Tom I'm very sorry if I've upset you, that certainly was not my intension. After all this is supposed to be a "HOBBY", from which one is to derive pleasure. I would not wish to take my pleasure at the expense of a fellow Ham. As I'm a bit long in the tooth for making impressions I am sorry that you should mistake that as my motive for taking up this topic.

> It may be fun to add and subtract all day, but to be useful in solving
> problems it is critical we know what data to use and how to use it.

There, in the true spirit of Ham Radio, you can help me Tom; keep me on the straight and narrow by not only pointing out the error of my ways, but where a correction is required supplying the correct data and substantiating it so that I may follow through and do better the next time.
After all in a contest it would be your word against mine without some supportive evidence.

It means Ideas.

> those(1) = people not as expert as old hands???

You chopped that one word short and changed the meaning Tom.

The old hands like to think that after devoting so many years they are expert.
However when I get around to thinking that I know it all will be the time for me to give it away.

With everything known what is left to be done?

> they(2) = does this mean old hands or those(1)???

What it means is what it ses:

"As for exercising ideas, they are intended as thought provokers for those not as expert as the old hands that like to think that they are; sort of one stage further than RAE revisited"

I am firmly of the opinion that a large number of Hams put in just enough study to qualify for a licence and then never look at another text book or consider the wonder of playing with nature ever again. Many think that the Radio Amateurs Examination is the pinnacle of learning; whereas it is not even the foot hills to the high country beyond. Why they deprive themselves of the greater pleasure by becoming just train number collectors I have never been able to understand.

In humility, 73

Tom, W8JI wrote:
"After all, you are saying the magnetic field will pass freely through the metal shield."

That is what metal Faraday screens do.

Tom`s implication is that the statement in quotation marks is untrue. Tom also implies Terman is not to be trusted, that his books had to be revised to correct mistakes, thus new editions were required by errata. Tom says magnetic and capacitive coupling are "inseparable". So, I requote another authority.

B. Whitfield Griffith, Jr. in "Radio-Electronic Transmission Fundamentals" wrote:

"The process of radiation is not the only means by which energy can be transferred from one circuit to another; if the magnetic lines of force which arise from the flow of current in one circuit happen to pass around, or link, the conductors of another circuit, then there is a mutual inductance between the two circuits. If this mutual inductance is of Lm henries, the voltage induced in circuit 2 by the flow of I1 amp in circuit 1 will be

E2 = j omega Lm I1 volts

Similarly, if the electric lines of force arising from portions of one circuit which are above ground potential terminate upon portions of another circuit which are separated from ground by some impedance, the resulting capacitive coupling will allow some interchange of energy between the two circuits. Both the inductive and capacitive types of coupling can be controlled by the proper application of shielding"

Griffith goes on to present a Faraday screen to eliminate capacitive coupling. Then, he presents a total shield for EM waves but uses a capacitor between two circuits to allow capacitive coupling while disallowing magnetic coupling between two circuits.

In other words, inductive and capacitive coupling are SEPARABLE. Tom is wrong.

Best regards, Richard Harrison, KB5WZI

> astronomers probably go to great lengths to differentiate the two.

As a matter of fact the signals from distance sources is excess noise.
For amny years they looked at the tiny excess by using long time constant integrators and Misee Pulsars completely.

In the case of the interferometer a large aperture may be simulated by using two or more AE separted by a large distance; say the width of the Pacific Ocean.
The noise may be sampled at either end of the interferometer by using atomic clocks and digitally recording the noise at sample intervals. At a later time the two recordings are combined on a computer and the data is time shifted one with respect to the other until a correleation occurs, (a peak in the excess noise or a dip in the excess noise on both recordings, like a code), at that time when corelation occurs the inteference pattern may be analysed and the nature of the Radio source determined, is it a single body or multiple body etc. The apparent diameter etc.

> If they didn't, they'd be listening to their own ears.

If you have ever been out in the open, (400 miles from the nearest person) you can in fact hear your own ears in the silence, if you concentrate it becomes deafening.

Of course you can also fool yourself very easily when listening to noise hour after hour. I have done this on a number of occassions when a Spacecraft has either been commanded down or may have been damaged (Marine VIII) or the solar panels cracked in the lunar night, (Surveyor). and you attempt to awaken it to ensure that it is infact dead. a long and tiring vigil. Reminds me of when I was a kid and listened night after night for a VK without much luck, and finally a little luck. Of course all that noise could have been avoided if I had listened in the early morning instead.

Cortland missed the point and introduced another ploy- the comparison to T-hunting.

My point was concerning his distinction between "Normal" and "Perpendicular"- Have I missed a distiction that he did not describe very well, or is there another confusion? In my book, "normal" and "Perpendicular" really mean the same thing(in his original sentence) and have nothing to do with "vertical" and "horizontal".

Puzzled- Bill-W4BSG

No, this is not a problem. The electric field incident on a tunnel mouth is
vertically polarized and the tunnel is horizontal. The T-hunters setup uses a
vertical tube.

I know what you mean. When I put attenuators over my ears (the name of the things won't come to me right now) I can hear what appears to be white noise, and also I can hear my own pulse.
As a child, I'd sit in my basement reading next to the furnace, a forced air unit that made a fair amount of noise. I noticed that my mind would make familiar phrases out of the noise, like the sound of my mother calling my name.

Hi Gary,

To the first paragraph above I would add that you can also hear your
own heart beat.

To the second, well, that reminds me of my time at sea looking at the
radar, seeing only sea return (white noise), and being convinced there
was a "skunk" (our term for a contact) out there, but no, over there,
nope - actually over there - nope not there but here.... And then we
happened upon a fishing fleet within a squall (I could see the
squall). The Captain screamed back to CIC, there's a vessel off the
port bow! We had to explain that wood does not show up very well on
radar (the fleet was not metal hulled) as we finally began to pick
them up within 3 miles of us. It was a very poor radar (mostly for in
port navigation - Raytheon Pathfinder). Actually, it took all of 15
minutes of nervous observation and then we were back in the noise.

Message-ID: <28244-3ABBB0E8-36@storefull-111.iap.bryant.webtv.net>
Source record: 167727

Andre seems to want to use a parabolic antenna to simultaneously receive three different broadcasts. This is practical if the signal sources are in the same general direction.

How different they are in direction determines the directivity and thus the gain which can be used. If the sources are in very nearly the same direction, a large dish with high gain and directivity can be used.

So, here is an example of a parabola with a diameter of about 3 wavelengths. The gain can be about 12 db. The beamwidth is about 30 degrees. The bandwidth is about 12% of the center frequency.

These data may be inapplicable to Andre`s case. We don`t have enough information.

Best regards, Richard Harrison, KB5WZI

It's not an argument, Leland, it's a fact. It is only considered an
argument
by those of you who have some reason to ignore the facts.
Only by learning it, gaining skill in how to do it, and working
radiotelegraphy can you come to know the essential facts concerning it
as a working communications mode.
You codefree types would much rather not even consider it to be a
communications mode, and for darn sure you would never bring yourself to
acknowledge that it is truly the most simple, easily implemented mode of
radiocommunication, useful under the most wide range of daunting
circumstances when virtually all other modes in common use are in the
toilet, or not even available due to their heavy overhead amd
infrastructure requirements. Nothing else even comes close.

So don't try to convince us that you will ever be a "Real Ham" ï¿½ until
you, too, are at least minimally qualified as a CW operator. Till that
time you will be an Amateur Radio licensee.

when they go bad they start slapping around the rotor and extorting protection money!

spiders can get in the small holes and their nests collect moisture and short out the trap. lightning could blow them. on some cc beams they use a steel screw to connect loading coils to the elements, the screws rust and make poor connections(replace with ss bolt and seal from wx). vibration from wind (even light breezes) could fatigue the wire or connections. pollution (say from a nearby furnace or fireplace flue) can get in and corrode them, salt mist from nearby oceans can get in also.

Hi Steve,

IR conforms to every convention of beam forming, gain, and radiation
patterns. It is in fact because of Optics that antenna
characteristics have the qualities we describe. You cannot then turn
and deny IR having those same attributes.
>> >This "radiation" however is not the form of radiation
>> >as defined by general antenna theory (gain, radiation patterns, etc).
IR is radiation (how many forms are there?), no qualifiers are
required or implied. Maxwell's equations are standard study in the
field of Optics and fully consistent with all applications at all

scales and frequencies.

This objection is, of course, null and void if the IEEE has kidnapped
the term Beam to deny its earlier usage relating to light.

>My choice of wording might have been poor.
Try again with better words.

>The point that I was trying to
>make is that we define the antenna's radiation properties in terms of how it
>radiates the EM energy delivered to its terminals.
There is no failure of logic when IR is brought to the table. There
are only three differences that could be drawn from this.

1. IR does not radiate in the same pattern. This is fully consistent
with the scale of the radiating structure and the scale of the
radiation wavelength. At IR, the physical structure is easily a
billion wavelengths in size. There should be no surprise that in
conforming to conventional antenna theory that such radiation is
omnidirectional. This does not disqualify IR as being a source of
radiation.

2. The modulation products are suppressed by the radiating structure
presenting thermal mass that acts as a low pass filter. This does not
disqualify IR as being a source of radiation.

3. IR radiation is not at the same frequency. - Duh - This does not
disqualify IR as being a source of radiation.

All merely concede the fact that IR finds itself in a poor radiation
system. And here we observe the irony of discussing the efficiency of
dissipation (which is a real consideration for engineers, I had a
dissipation budget for my flight data recorder design). This is also
classic consideration when you go out and buy heat sinks - they too
are engineered to "match" loads of Thermal Resistance.

5659. Re: Faraday shield antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-23 22:05:53 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3ABBC8C1.9BCFEF80@eznec.com>
Source record: 167732

I really hate to see such a fundamental misunderstanding get perpetuated, so I'll stick my head up again.

Maxwell's equations say that it's impossible to have a time-varying electric field without also having a time-varying magnetic field, or vice-versa. No amount of shielding or other manipulation can change this. If any "expert" seems to be saying otherwise, either the "expert" is being misinterpreted (most likely), or he's just plain wrong. I'm sure it's this fundamental, irrevocable relationship that Tom refers to. To dispute it is to dispute Maxwell's equations, which have worked well for all of us since their formulation.

Now, it IS possible to change how much of the energy in an EM wave is in the electric field and how much is in the magnetic. The ratio of E/H is called the "field impedance" or "wave impedance", and this doesn't have a fixed value. In free space, far from a radiator, all fields have an E/H ratio of 120*pi, or 377 ohms. But in other media, or close to a radiator, they don't. The field very close to a short dipole has a high E/H ratio; very close to a small loop, the E/H ratio is low. This, I suppose, is why small loops are called "magnetic loops" by amateurs. Small loops don't respond to just magnetic fields, or dipoles just to electric fields. If you apply a signal to a small loop, what happens? Very close to the loop, the E/H ratio is low. But as you move away from the loop, the E/H ratio increases, to a value actually higher than 377 ohms. This typically happens at a distance much less than a wavelength. Beyond this distance, it decreases, to finally approach 377 ohms. (A short dipole does exactly the same thing, but with E/H starting out high, reaching a minimum at much less than a wavelength, then increasing again to approach 377 ohms.) Reciprocally, if a wave from a source a wavelength away approaches the loop, the ratio of its E to H field decreases very close to the loop. If the source is very far away, it doesn't matter what kind of source it was. For example, suppose we apply a signal to a small dipole. Near the dipole, the E/H ratio is large, but at, say, half a wavelength away, the E/H ratio is nearly that of free space. If we apply the same signal to a small loop and look at the field a half wavelength away, we see essentially the same E/H ratio as for the dipole. So we can't tell, at that distance from the source, what kind of radiator the field is coming from. Now let's receive that signal with a short dipole and a loop. As the wave approaches either antenna, the E/H ratio changes appropriately for that antenna. The result is that both will receive the signal equally well. The small transmitting loop produced a dominantly magnetic field (small E/H), but only very, very close to the antenna. Beyond that, it looks like the field from any other antenna.

The following values are illustrative. They were calculated for a 2 meter circumference loop and 2 meter long dipole at 3 MHz, done with EZNEC's near field analysis. Anyone with EZNEC, even the demo version, or other modeling program capable of near field calculations can duplicate these results. The results have been confirmed with another analytic technique. The first column is the distance from the center of the antenna. The values in the second and third columns is the field impedance in ohms at that distance.

Meters Loop Dipole
2 54 2622
4 104 1363
6 164 862
8 237 597
10 323 440
12 411 345
14 486 291
16 534 265
18 553 257
20 550 258
22 537 264
24 521 273
26 505 281
28 491 290
30 478 297
50 415 342
100 386 368
150 381 373
200 379 374
250 378 375
300 378 376

Thinking of the loop as a receiving antenna, you can see that if a source were a couple of meters (1/50 wavelength) away, the loop would respond more strongly to the magnetic field produced by that source, since the field impedance is lower than 377 ohms. Two loops placed 2 meters apart would couple well, and a dipole and loop would couple poorly. But look what happens in the region 12 meters (about 1/8 wavelength) and beyond -- the loop is actually more responsive to the ELECTRIC field, and the dipole to the MAGNETIC field. This technically holds true at all distances greater than about 1/8 wavelength, although the difference becomes insignificant within a half to one wavelength or so. (The exact place this reversal takes place depends on the size of the antenna in wavelengths.)

Many of the references cited by Richard have dealt with the shielding of transformer windings, where the source and receiving radiators are separated only by a tiny fraction of a wavelength. In this case, each is well within the other's near field, and the field impedances can be extremely low. Looking at the situation, you could reasonably say that the electric field is negligible in most cases, and treat the magnetic field as though the electric field were zero. And you can alter the wave

impedance by shielding. That is, you can alter the E/H ratio. But to say you can completely exclude one field without excluding the other is to contradict Maxwell's equations.

Again, care should be made in making comparisons. Two transformer windings spaced a few millimeters apart at 60 Hz isn't at all a good example of what happens when receiving a signal from many wavelengths away with a small loop.

Tom has run some experiments showing that the reception of shielded and unshielded loops is the same. Do any of you who claim that the shielding has an effect have experimental evidence to the contrary?

Better words:

The radio frequency electromagnetic radiation characteristics or properties
of a radio frequency antenna are described or characterized based upon the
manner in which the radio frequency antenna radiates the radio frequency
electromagnetic energy delivered to its terminals. A lossy radio frequency
antenna will also radiate Infrared electromagnetic radiation as a result of
converting some portion of the radio frequency electromagnetic energy into
"heat". The Infrared radiation will obey the boundary conditions and
relationships established by Maxwell's equations. However, it is unlikely
that the antenna's radiation properties at the IR frequencies, in terms of
pattern shape and gain, will identically match the antenna's radiation
properties at the RF frequency.

> >The point that I was trying to

>

- Duh - ????? Well, - Der - IR is not the "source" of radiation. It is
the portion of the EM frequency spectrum at which the radiation occurs.

I am under the impression (if I am wrong I am certain that you will correct
me) that the source of Infrared radiation is the billions of vibrating
electrons in the object radiating at IR. These electrons vibrate because
they are at a higher state of energy. The technical term might be "heat"

Talk to you soon,

Steve

You can find what information is available at:
http://members.home.net/wdpushie/antennas.htm The data is somewhat
old now, but I think it is still valid. There are no lab reports,
just subjective comparisons as to how far away from repeaters you
could still maintain contact. You can also contact the club President
directly. Info on web site. He loves to talk antennas.

The HP32 may have been superseded by something else. If you check
around on the site it may explain what. I dropped out of MARC a few
years ago when we sold our Gold Wing so haven't kept up on the latest
with them. They have tons of good information relative to motorcycle
mobiling which is applicable to use in automobiles.

Nevia:
Could you be a little more descript about the duplexer? My sinclair catalog does not list it.

Basically there are two common types of duplexers, the hybrid ring and the pass/reject type.
The hybrid ring as a closed ring phasing harness for each cavity and there are coaxial taps on it to interconnect the rings. The cavities have only one port vs two for the pass-reject type.

Sinclair discontinued the hybrid ring sometime in the mid 80's and no longer supports it
It was too costly to manufacture and provided no out of band attenuation thus requiring additional filtering..

You did not state the dimensions of the cavities. Generally speaking the larger the can, the higher the Q. Most are about 7 inches in diamter and about 26 inches in length.

For two meters and the 600KHz separation at your power level, you need a duplexer with at least 95-100db isolation to avoid desense. To get this sort of separation you need at least a six cavity duplexer of the pass/reject type. The best results that I have ever been able to acheive was 80 db with only four cans It is simply not enough.

The four can hybrid ring variety can get you over 120 db of isolation if properly tuned. The dimensions of the phasing harness are critical and most commercial band duplexers will not work in the two meter band unless of course you manufacture new harnesses for the frequencies you want to work.

Also there are no standardized input to output frequency offsets for the 152-174MHz band and if this duplexer came out of commercial service it may have been setup up for a megahertx or more separation in which case it probably worked well.

>

Actually, the price the FCC sets is based on international treaty. Of course, that treaty will likely change in the next few years by dropping the code requirement, and the FCC will follow suit. Those that want HF priviledges will either pay the price and learn code or they can simply wait a few years until HF priviledges go on 'clearance'.

Nevia:
Could you be a little more descript about the duplexer? My sinclair catalog
does not list it. I assume it is a reslock type which is a pass/reject type. Reslock duplexers were popular for VHF mobile telephone use because of their compact size. I have never seen one successfully used for two meter repeater duplexing.

Basically there are two common types of duplexers, the hybrid ring and the
pass/reject type.
The hybrid ring as a closed ring phasing harness for each cavity and there are
coaxial taps on it to interconnect the rings. The cavities have only one port
vs two for the pass-reject type.

Sinclair discontinued the hybrid ring sometime in the mid 80's and no longer
supports it
It was too costly to manufacture and provided no out of band attenuation thus
requiring additional filtering..

You did not state the dimensions of the cavities. Generally speaking the larger
the can, the higher the Q. Most are about 7 inches in diamter and about 26
inches in length.

For two meters and the 600KHz separation at your power level, you need a duplexer with at least 95-100db isolation to avoid desense. To get this sort of
separation you need at least a six cavity duplexer of the pass/reject type. The
best results that I have ever been able to acheive was 80 db with only four
cans It is simply not enough.

The four can hybrid ring variety can get you over 120 db of isolation at 600KHz if properly tuned. The dimensions of the phasing harness are critical and most
commercial band hybrid ring duplexers will not work in the two meter band unless of course
you manufacture new harnesses for the frequencies you want to work.

Also there are no standardized input to output frequency offsets for the
152-174MHz commercial band and if this duplexer came out of commercial
service it may have
been setup up for a megaHertz or more separation in which case it
probably
worked well for that service.

In tuning a duplexer you should never use transmitter power to do it.
What I do is to use a sensitive receiver with an S-meter and a signal
generator with a calibrated attenuator. I separate the cans and tune
them one at a time and set the pass properties for minimum attenuation
and the reject notch for maximum attenuation using the appropriate
frequecies, of course.

Good luck with it and 73...Dick K7RNZ

Isn't that why there are revisions? To make things clearer, and to correct errors? Or am I mistaken?

Actually Terman isn't the problem, other than his unfortunate use of some words that can be confusing.

The problem is you are extracting information about coupling inside transformers and small closed systems, and applying it to antennas.

Terman clearly was not discussing antennas in the text you quoted.

>Tom says magnetic and capacitive coupling are "inseparable". So, I
>requote another authority.

That is another example of how you change words to suit your own ideas. I never said that, and you can not copy and paste where I did.

In the above text, the author clearly states he is talking about linked systems. Again you are using text describing transfomers as an explaination about antennas.

You'd better wake up and get on the right page. I long ago stated the boundary was a few loop diameters away.

>In other words, inductive and capacitive coupling are SEPARABLE. Tom is
>wrong.

Must be another "Tom", this Tom never said inductive and capacitive coupling were the same.

This Tom simply said you can not shield a loop and alter its field impedance. You can not change its response to time-varying electric fields at any distance from the antenna...other than the change offered by improving or changing the system's balance.

There shouldn't be any confusion; and if there is, the confusion is
about T0.

In modern definitions of noise figure, T0 has no relationship to ambient
temperature - it is simply an arbitrary reference temperature. (T0 is
defined as 290K, but you could construct a completely self-consistent
definition of "noise figure" using any other reference temperature above
absolute zero.)

Tom, sorry to say I have to agree with your assessment.

Waffle, waffle, waffle, bafflegab, etc., may sound very impressive.
But when nearing the bottom line it becomes necessary to put some
numbers into the equations, and there are no numbers forthcoming,
the whole thing collapses like a pack of cards.

Hi Steve,

Forgive the stern admonishments - levity is welcome.

Consider this from the Encyclopedia Britannica:
http://www.britannica.com/bcom/eb/article/printable/8/0,5722,108498,00.html
"Normally the electrons, subjected to a force because of an
electric field, accelerate and progressively acquire greater speed.
Their velocity is, however, limited in a wire because they lose some
of their acquired energy to the wire in collisions with other
electrons and in collisions with atoms in the wire. The lost energy is
either transferred to other electrons, which later radiate, or the
wire becomes excited with tiny mechanical vibrations referred to as
phonons. Both processes heat the material. "

I hope you will note that heat occurs as a product of both processes
and that one process will allow that heat to radiate and one (phonons)
not. Again, this is what I speak of when I mentioned the irony of
the efficiency of dissipation (and hence the deeply buried humor of my
previous post). As RF Photons, in times and threads past, were so
wildly fanciful in their discussion, I hesitated to bring up the
issues of dissipation efficiency and Phonons (which are truly
vibratory - and described as extremely high frequency sound).

The IEEE definitions fall far behind the curve of current science of
heat. Hardly surprising for a dictionary that appeals to heat to
explain dissipation, but cannot, in turn, define heat. As for this
cynical observation, I must defer to Cecil and his copy (for which I
believe he supported this claim). Cecil, am I wrong? Even more, is
there an entry for Phonons?

Why do most people find it necessary to quote Terman ? Did he
write the radio hams bible ? I thought the ham's bible was a
compendium of the ARRL publications over the last 75 years.

If you can't provide a logical argument to illustrate your point
then you automatically lose the argument by dragging in Terman for
support. Why not just quote Terman in the first place ?

Bill;

A comment you made below seems to fit the solution to the problem. If the code test was made part of the scoring of the written test just like the various segments of the present written then those who want to do code can study the code and have a section of the test that they will pass and have other sections that they can slide on and still get their passing grade.

Common sense and basic survival instinct are completely different than
trying to impose your personal opinions to the general public on a subject
in which you have no first hand knowledge or experience.

A perfect example of this is the anti-gun crowd - the vast majority of them
have never even fired a gun, and yet they would have you believe that based
on their feelings and opinions, you should have to give up your guns.

I understand how a nuclear reactor works, but I would never be allowed to
testify in court as to the value of such a device to the general public.
This is because no matter how well intended, the fact remains that my
opinion on the subject is moot due to the fact that I do not possess the
expertise necessary to present a legally valid opinion.

Planning on installing HF in the car.

I am planning on using a IC-706 feeding a 108" CB whip VIA a automatic antenna tuner. I have a friend out there using this configuration, He has instant access to 80M-6M via the tuner.

My question is... Is there anyone else out there using this? How does it compare to other antennas...

I'm interested in any side by side results anyone may have..

Thanks
James Hilins

>then this should reduce the SWR?

Impedances are another issue. What you have are a bunch of half-wave
sections that radiated (the outside of the shields) fed by being tied
across a transmission line at points that are out-of-phase.

If the outside of the cable isn't 1/2 wl long, it is reactive.

If it is 1/2 wl long (electrically) it is resistive....but what is the
impedance end-to-end? How do all those 1/2 wl sections share current?
What is the total impedance of the whole system?

I can't answer any of that without days of work, I can only describe
how it works. My guess is that the engineering is more complex than
the people who copied the antenna ever knew.

I've know several people who tried to build the antennas, and no one
who ever actually made one work with reasonable gain.

>velocity factor? Presumably if the tubing has a VF of 0.66 then the antenna
>should work - even if the losses are high? I have a table somewhere that

VF also depends on how thick the dielectric is, compared to the air
the field passes through.

I read the full excerpt from the quoted web page and it was clear that it was about dissipation of energy in a wire in the form of heat (electrons colliding - vibrating was another poor choice of words on my part). It was not clearly defined as to what they meant by radiation. At this point, I am assuming that it was referring to radiation in the IR portion of the EM spectrum.

> there an entry for Phonons?
>

Quite honestly I have not read the IEEE Dictionary.

Heat is an energy conversion process where electrons (phonons, whatever) collide with one another. It is considered energy lost. This lost energy is transferred to surrounding objects in numerous ways. Convection, conduction and Infrared radiation. Because the human body detects thermal convection and conduction, we perceive and generally define heat in this manner.

Infrared radiation is also a heat transfer process, where energy is transferred to the surrounding environment through EM radiation. The transfer of energy as Infrared radiation is beyond our detection abilities so we don't perceive it as "heat".

Given that that IR is a heat transfer process as is thermal convection and conduction, the IEEE definition for dissipation being a conversion of energy to heat is accurate.

I used to live in a small country town when I first got into ham radio. Lacking the funds to put a "gosh almighty" tower and antenna system I opted for a Cushcraft Antenna all band vertical. It was put on the South Side of the house and sat there faithfully for about seven years. When I took it down I noticed that the wind, carrying "elements" in the air, sand, dirt, ice and snow, had taken it's toll on the coverings of the traps. I replaced two that were really nasty and cleaned up the trap itself with new fasteners and heatshrink tubing. If the covering is not in bad condition you can, with a hobby knife, cut away carefully where the connections are and do the housekeeping needed. Have fun. 73 W9FPJ

Hi Steve,

ALL that you wrote (and which I did not include) is absolutely true.

The specific point is that we are pivoting about the meaning of
dissipation which has been identified (by some) to mean NOT radiation.
It is this error to which I am responding.

You will have better results if the automatic
tuner is connected to a center-loaded whip antenna
that is tuned reasonably close to the band you want
to operate.. the tuner will then re-resonate the antenna
system as you tune from one segment of an amateur
band to another .. this would be especially effective
on the lover freqs such as 75 and 40 meters..

An 8 or 9-foot whip, with no external loading coils,
will be very inefficient on these lower frequencies when
the automatic tuner is trying to re-tune a short whip.

Moving most of the loading to the center of the whip allows
better radiation efficiency from the lower 1/3 of the antenna's
length which is where most of the real radiating is being accomplished..

It isn't quoting Terman, or anyone else, that is the problem Reg.
The problem is quoting out of context.

Terman's (and other's) discussion of common mode coupling, because of a lack of up-close balance, is somehow being misapplied in a vain attempt to prove the silly notion that adding a shield to a loop somehow changes the field impedance of the loop, or causes the loop to not respond to time-varying electric fields.

The best example I can think of is a small loop antenna I did for a medical application. The 27.120 MHz loop antenna was in a small pan, with a plastic cover. Inside was a single layer spiral with a flat plate parallel to the pan attached at the center. The outer end was grounded, and the spiral was shunt fed.

The flat plate was made into a variable capacitor by being tuned with a "flapper plate" that was grounded to the pan.

Over the top of this whole mess, I had a Faraday shield etched on PC board material.

What the Faraday shield did was prevent the capacitor from coupling to the hind-end of the test subjects. (I was required to use the rear end of average-build females between the age of 18 and 40 as the standard load for impedance matching.) The radiation fields outside the loop weren't changed one iota by the shield. Either measuring with an E-field probe or an H-field probe two feet away the results remained identical. Hamburger, saline solution, or a probe inside the test subject all indicated exactly the same E and H fields just inches from the loop shield or no shield.

The only thing that changed is the capacitor was not detuned as much when a fleshy object (or saline solution) was placed 1 inch or less away from the capacitor.

Now I could have handled that problem ten different ways and had the same results, but this was mechanically the easiest. The applicator received and transmitted exactly the same way, it was only near the loop...where system balance was screwed up like a rubber watch...that things changed.

As a matter of fact I had another loop that simply inverted the position of the grounded and hot plates that produced identical results. That applicator could be placed against the same target, and it wouldn't detune any more than the Faraday shielded applicator. It wasn't used because it wasn't as easy to build.

As a matter of fact to get maximum nulling of stray capacitance, the Faraday shield had every other "wire" run in from the opposite edge. It was double-sided board, with the opposite face traces rotated 90 degrees. Without balancing the shield this way, it made almost no difference at all in the effect when something was placed near the applicator!

Why people think this common-mode balance problem extends beyond the immediate area of the antenna, or somehow changes the response of the antenna to sources more than a loop diameter or two away is beyond me!

Hi Richard,

I think the conversation with you, Dennis and the group has been interesting. I have always thought of dissipation as lost energy converted to heat. Until going through this discussion, I have not really thought of dissipation in terms of any EM "radiation" occurring. I still prefer to use the term radiation to describe the desired radiation effect and dissipation to describe the energy lost. It is significant to not lose sight of the EM IR radiation process occurring with the heat dissipation process.

The only remaining point that I have issue with is describing the desired EM radiation process as a dissipation process. This may be a matter of semantics or personal preference.

That's it for me.

Steve

Try reading any of the books written by Don Johnson:

"40 Years of HF Mobileering"
"40 + Year of HF Mobileering"
"Everything You Wanted to Know About HF Mobileering but Forgot to
Ask".

He invented the DK3 antenna ...aka. Screwdriver.

IMHO, tuners make the radio Happy. Happy antennas (physically
"sized" to resonance) radiate. Location on the vehicle makes a big
difference as well.

Beat the CC&R's!!! Go Mobile!!!

5691. Antenna - restricted setup question

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-24 02:43:56 UTC
From: Bruno Quesnel <quesnelb@ve2.ele.etsmtl.ca>
Message-ID: <3ABC09EC.F9075F22@ve2.ele.etsmtl.ca>
Source record: 167765

Hi to all,

I'm in the process of renewing my HF antenna. The one I was using
was a Hygain vertical covering the 6-20M bands. I live in Montreal and
with the waether of the past few days, it fell down on the roof.
Unfortunatly, I can't asses the damages to the antenna, but will see
later.

Right now, I've got a old TV antenna tower that holds a VHF/UHF
vertical pretty fine for the past 2 years. I've also got a 3 foot
tripod installed for holding the HF vertical (It actually bent on the
mast holding the antenna to the tripod). The house dimensions is about
20X24, with the tower on one corner in the backyard.

I'd like to replace the vertical antenna with a orizontal type
antenna. You probobly saw my posting earlier asking for the MQ1.
Thanks for the response. Basically, I'm looking for a compact HF
antenna but horizontal. I've been looking at the 3 elements/tribander
yagis from the different mfg but I think that all the antennas are to
big for my setup.

Unfortunatly, because of the backyard organisation, changing the
tower for a free standing is pretty much out of the question (thermopump
on one side and the fence on the other). So I either need a light
weight antenna to fit on the tower or to invest in a quadpod to replace
the tripod on top of the roof..???

Or for the mean time getting a dipole would do a "decent job" (not
as a good job as a beam). Would the investment in a dipole be fair
considering my situation or other situation be good for the limitted
space I have ???

Thanks in advance to all

>Roy Lewallen, W7EL

Hi Roy,

Good of you to offer the clear balance in this debate.

As for your question, I cannot provide evidence to the contrary, but I would make an observation and pose my own question.

In the Nav, we had an FM radio in the lab that only played when the water-tight door was open (you are never far from saltwater soaked ground on/in a ship). It had the conventional whip antenna. If we had simply turned that to a loop antenna, then we would've been rockin'?

Ah, but the question smells of a bait, and I am trying to figure out why. It must be a question of what "shield" means.

For the loop alone, there are two ways to shield it.

1. The FM radio and loop occupy a toroidal conductive hollow volume.

2. The FM radio and loop occupy a spheric conductive hollow volume.

Any significance? For number 2, my own expectation is, no, my lab's FM radio with a loop in a conductive room would not work any better. This looks like Richard's shield. I cannot attest to the efficacy of shield 1, which looks like Tom's shield (or this is just guessing in the extreme).

I posted this a couple of weeks ago. Here it is again - perhaps it
will be helpful to you:
==========
Hi All,
For those who contemplate HF mobile at some point I thought you'd
be interested in this comparison between a couple of different HF
mobile antenna systems.
I compared a Radio Shack 102" stainless steel whip ($14.99) and
Icom AH-4 autotuner ($309.95) to a center loaded antenna called the
"Carolina Bug Katcher" ($99.95) from Lakeview Antennas
(www.hamstick.com) Since the whip is only resonant on (or near) 10m I
used the Icom AH-4 tuner with the whip. The bugcatcher, which covers
40-10m, doesn't need a tuner, but I left the tuner in line anyway just
to keep the system the same all the way back to the antenna mount.
The purpose of the exercise was to see if the whip and tuner would
be an acceptable alternative to the bug catcher. The whip/tuner is
nice because I can change bands without stopping the car and changing
coil taps. This is attractive when it's cold/rainy/dark. Also, the
whip isn't as "ugly" as the bugcatcher, or at least that's what my
daughter says. But beauty is in the eye of the beholder.
The test setup was as follows: The radio was an Icom 706Mk2G
mounted in my car. The antenna mount is on the rear bumper. Each
antenna was tested on the same mount, same feedline, etc. In other
words, the system was the same except for the actual radiator being
compared. I parked the car in a large open area away from other
vehicles, and used a COM-120B service monitor in the lab at my office
to monitor the field strength. I then transmitted a carrier on each
band with each antenna with the radio set to the same power level. A

friend of mine recorded the field strength readings on the spectrum display on the service monitor in the lab. Here are the results:

Band Bugcatcher Whip Winner
==== ========== ==== ======
40m -62dBm -76dBm Bugcatcher, by 14dB
30m -64dBm -76dBm Bugcatcher, by 12dB
20m -44dBm -52dBm Bugcatcher, by 8dB
17m -66dBm -74dBm Bugcatcher, by 8dB
15m -59dBm -69dBm Bugcatcher, by 10dB
12m -50dBm -58dBm Bugcatcher, by 8dB
10m -58dBm -56dBm Whip/tuner, by 2dB
6m -65dBm -64dBm Whip/tuner, by 1dB

Note: The readings are likely subject to an error or a dB or two. But the data tells a pretty convincing story, and should probably come as no surprise. Base loading just can't compete with center loading when it comes to efficiency.
Using 100w into the whip on 40 and 30m (the bands I use most) would be like running only 4 or 5 watts with the bugcatcher. Or put another way, I'd have to run over 2500w on the whip to match the bugcatcher's 100w signal. It's not until you get to 10m and 6m (where the whip is no longer electrically "short") that the performance is similar. And of course, the gain of the bugcatcher is there on receive as well. You can't work what you can't hear.
Your mileage may vary. Comments are welcome. The usual disclaimer applies - I have no association with any of the companies listed here except as a customer. Also, the Carolina Bug Katcher is no longer available according to Lakeview's web page. But a similar antenna is available from Henry Allen K5BUG at www.texasbugcatcher.com
73,
Doug, K4DSP/M

Roy, W7EL wrote:
"Two transformer windings spaced a few millimeters apart at 60 Hz isn`t at all a good example of what happens when receiving a signal from many wavelengths away with a small loop."

OK. Suppose we have a couple of r-f coils sited end to end on the same axis and close enough for cnsiderable mutual inductance (coupling). That is, that current in one coil generates a voltage across the other coil. If we put a metal box around one of the coils and ground it, coupling between the coils is nearly, if not completely, killed. Why?

The electric charges in the directly excited (primary) coil produce electric field lines of force which end on the shield and it shorts them out so they can`t act on the secondary. We make symmetrical ground connections so the charge equalization current has no effect.

Well, the shield ends the capacitive coupling between primary and secondary, but why does the metal shield kill the magnetic coupling between the coils?

The short answer is Lenz`s law. Lenz says that induced current in a circuit must produce a magnetic field which opposes its creator. If the shield is perfectly conducting, the opposing field equals the field which produces it. Aluminum is an imperfect conductor, but it is good enough for most r-f shielding purposes, and it is economical.

So, we see that a solid conducting shield can inhibit both electric and magnetic r-f fields. Such shields are seen almost everywhere. If they didn`t so work, they wouldn`t be so used.

We should all be aware of the Faraday screen (shield) which is designed to thwart Lenz`s law from a macro viewpoint, so that the metallic shield becomes porous for magnetic coupling between the primary and secondary coils in our example.

Bars or wires shorted together on one end and grounded, but insulated from each other at the other end, can sieve out the electric field while allowing the magnetic field to pass right through. Millions of Faraday shields are installed and doing their job. There is no need for investigation. This is a long proven practice. Once again, the Faraday screen`s purpose is to block capacitive coupling while allowing magnetic coupling.

By breaking the circuit in the shield for a circulating current, the shield can`t produce an effective opposing field and the magnetic coupling of primary and secondary is accomplished.

So, the declaration that separation of the magnetic and capacitive coupling is impossible and that the fields are inseparable is wrong. No matter who says it or how many times.

This has nothing to do with propagation of radio waves in a vacuum or even the basics of a loop antenna. It (the Faraday shield) is just a block to the electric field. The propagation of waves in the vacuum does require that each wave be in operation to beget the other half of the energy transport pair. E&H are both essential. But we can kill one and the other regenerates its partner. We short and open transmission lines, don`t we?

An antenna can be equipped with a Faraday screen to block an electric field while allowing magnetic fierld excitation, just as happens with the Faraday shielded coil. A Farady shielded secondary coil`s induced current simultaneously produces a secondary voltage, and the electric force field that goes with it.

A Faraday shielded antenna might just as well be a transmitting antenna. We know the E field of an antenna comes from its high-voltage points, while its H field comes from its high-current points. By ohms law we know that high-impedance is associated with high-voltage and low-impedance is associated with low-voltage. We also know that low-impedance antennas radiate just as well as high-impedance antennas. In the radiation process everything works out and the impedance of the wave adjusts to 377 ohms and the E&H fields regenerate each other as required.

There is no problem of blocking the electrostatic influence of signal, noise, and miscellaneous discontinuities by using a Faraday shield on a small loop antenna.

Best regards, Richard Harrison, KB5WZI

So all the digital communications experts who don't possess actual
Morse code skill don't know the "essential facts" about Morse code?
If Shannon didn't possess Morse code skill, do you think he didn't
understand the theory? You think the FCC doesn't understand Morse
code? You're still beating that poor old dead horse. Hams who want
to use Morse code use it. Hams who don't want to use Morse code
don't use it. Every ham has a choice of his/her favorite mode(s).

It works pretty well on 20m-10m. It works better if you use a three
foot bottom section to extend the whip to 12 ft. It was one to two
S-units down from my homemade bugcatcher on 40m and 3-4 S-units
down on 75m, i.e. near worthless.

Richard Clark wrote:
"---reminds me of my time at sea looking at the radar---."

Our radar operation was comical, too. It was a Raytheon SO-2 "navigational radar". We kept the spare magnetron in the ship`s safe because it was considered a war secret, part of a secret weapon.

We often traveled in convoy. The problem was maintainng position in the convoy when those on watch were drowsy. We had several close calls when we almost ran down the ship ahead of us.

I got an emergency full astern call in the engine room one night. At sea we customarily switched off power to the prop shaft brakes because we would not be maneuvering, and they consumed a lot of electrical power even on stand-by. The engines were 10-cylinder opposed-piston Fairbanks-Morse locomotive engines. We reversed shaft rotation by stopping the engine, shifting the lobes on the camshaft and restarting the engine in reversed rotation. Well, in the crisis, I forgot about the shaft brake and just reversed the engine. It cranked, started, and ran fine except for a big bang when I admitted the starting air, and the engine room immediately filled with smoke, an oilly mist , water vapor, and who knew what else. Couldn`t see a thing for a while, but everything ran all right. After some years, I figured it out. I blew the overpressure valve on the starting-air system and emptyed all the crud in the air bottles with extreme engine cylinder pressure.

The bridge watch would wake up, scream down the voice tube to the radar operator, and desperately ask te distance to the vessel ahead. The radar operator would arise and dutifully go stick his head out the porthole and return to scream his estimate back to the bridge. Due to the sea return (ground clutter) there was no way to get a valid radar distance reading in such close quarters. But everyone kept up the pretense.

Well obviously I did not consider that your data neither answered my
question nor supported your contention that I was taking too hot a value for
the sky temperature, despite several references to the contrary; so let me
put the question to you straight so that there shall be no
missunderstanding.

What do you make the sky temperature at 1.75 MHz?
What is the measured efficiency of the Antenna that you use to measure the
sky temperature.

I'm afraid that your quotation of the signal level in a bandwidth without
some qualification is not prima facie evidence of sky temperature.
Certainly the numbers can be transformed to an equivalent temperature, but
by how much must that figure be modified to accomodate the inefficiency of
the measuring apparatus?

> How dare you imply that a "large number" of Hams are lazy.

I do not imply, I accuse,
just listen to the rubbish that is exchanged on air.

I attempted to give a short talk to a group of about fifty Hams, it was all
fundemental stuff on noise, yet apart from one Ham, (a profesional
Engineer), I was faced by a sea of blank faces, and no glimmer of interest
in an absorbing subject.
Hams that I encounter at rallies etc. do little to encourage me that any
seek a higher understanding of their chosen preoccupation.
In the main Hams are lazy, Hancock's lampoon is not so far off the mark.

However there are brilliant exceptions that go completely unnoticed because
it takes a little talent to recoginse genius.

> What is so special about you, that allows you to judge other people by
> what they do in life?

Fair question, there is nothing about me which is not present in any other,
all they have to do is dig a little to find it. I only lament the fact that
they have not had the good fortune to look a little further, to go that
extra mile.

> Please share all of your wonderful accomplishments in life with us, so
> that the poor deprived "train number collectors" among us can grovel
> at your feet.

Pr. 8:10 Take my instructions instead of silver,
and knowledge rather than choice gold;
11 for wisdom is better than jewels,
and all that you may desire cannot compare with her. -
RSV

Accomplishments:
For some of which SEE www.gary.peach.dial.pipex.com

I refer to train numbers because the bands are saturated with contest after
contest; the sum total of which is nil.
Contests could have a useful purpose to serve with some changes to the rules
and colation of the wealth of data that it would be possible to glean from
the logs of the contestants.

But for years that opportunity has been missed, and I suspect that apathy will assign contests to that roll for many more years. As such the Ham is just a train number collector accumulating worthless bits of paper that do little if anything towards the understanding of radio communication or physics.

Just what does the rubber stamp QSO acheive?

The man that issues a 599 knowing it to be untrue is a liar and a cheat.

How worthless it is to the genuine investigator that wants to evaluate some new antenna or equipment on air, what a time waster such practices are.

It is high time that we cleaned up our act.

Any just Ham will know that what I say is true and that I probably risk censure for being foolish to point out that the king has no clothes.

> That "humility thing" , it's a joke...right?

We have an idiom in England "to get up someone's nose",
I seem unintentionally to have done so with you Tom.

I am sorry that you feel that this exchange should degenerate into a personal slanging match. I will discuss technical topics without rancor, but this is the last exchange, (before your natural right to reply), on personal traits. To resort to such ad hominem tactics is to admit defeat, not that I ever intended this exchange to become a contest of personalities.

> temperature - it is simply an arbitrary reference temperature. (T0 is
> defined as 290K, but you could construct a completely self-consistent
> definition of "noise figure" using any other reference temperature above
> absolute zero.)

Quite so provided that everyone understands that and agrees with the figure
that you have chosen. (which historically they do). The value of 290°K is a
convenience because it is near or around the temperature to be found
normally in the laboratory or field installation and thus takes no
additional apparatus or plant to reach that temperature. Slight deviations
from 17°C make little difference in practice to the measurement of large
noise figures that were encountered at around the time when the whole system
was proposed. Perhaps in the light of low noise figure amplifiers being
readily available some revision of the agreed standards might be
appropriate, but unless the Ham fraternity wish to break away from the
accepted standards anything which is discussed here is unlikely to influence

the convention.

Ah! found an ally at last , or should I say comrade, Reg?

Perhaps you can help me out by filling in the un-known numbers instead of
sitting in the bleachers on your hands.
I know that you have measured the efficiencies of all of your antennae Reg,
so what do you measure the sky temperature at 1.75 MHz?
or at least near bye at 1.8 - 2 MHz.

The keyword here is "Hams". As used in your sentence, the implication is
that a person you classify as a "Ham" possesses the skills to use CW if
they choose to do so.

> Every ham has a choice of his/her >favorite mode(s).

Agreed, according to your definition of a "Ham". But what about those
persons who do not possess the skill to operate CW? They do not fit the
definition of a "Ham" as you use it here... because they cannot operate CW
if they wanted to because of lack of skills.

Which is basically what the whole discussion is about... There are some who
may have access to the bands, but since they do not possess the skills
necessary to operate CW, by definition they can't be included in the group
commonly referred to as Hams...

If you had a heart beat like mine you wouldn't listen, ther are ectopic
beats and listening can make the whole thing go haywire. Some sort of
positive feed back starts to occur, most unpleasent and it plays havoc with
the BP which drops rapidly because the pump becomes very inefficient, So be
warned, be careful.

Just think of the universe as one huge dummy load, the energy does
eventually decay into incoherent EM thermal form instead of remaining as
coherent EM radiation, but it does so slowly and geometrically and it is
shared over such a huge volume that the energy density becomes extremely
small at the point where it is no longer distinguishable from all the other
stochastic electromagnetic events.
I guess what characterises it is that it is a vector quantity with direction
as well as magnitude. The direction in the absence of a mirror keeps on
going away from the point of origin. In the case of a perfect mirror only
reflection takes place. In the more common case of an imperfect mirror some
reflection occurs and also some absorption which transforms immediately into
the non coherent form of EM energy - thermal energy.

It's a bit like a drunk on Pay-night, it (all EM radiation) eventually
becomes incoherent.

Entropy

5713. Heck with ARRL

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-24 08:02:01 UTC

Just why the heck would anybody in his/her right mind pay the ARRL to be a
member? For what?
Who cares?
The ARRL is losing members day in and day out. They have to ask themselves,
"Why?"

The real reason for this loss of members is simple.
1. It costs too much and you get nothing back.
2. The magazine is too full of voting and political agendas.
3. Nobody really cares about the ARRL.
4. The ARRL really doesn't care about you.
5. The ARRL has an agenda that does not help Hams.

>noise figure amplifiers being readily available some revision of the
>agreed standards might be appropriate,

Yes, you've identified the problem. 290K was originally chosen by Friis
as being conveniently around room temperature, which would be the
physical temperature of the resistive termination inside the noise
source. When typical noise temperatures were up in the thousands of K, a
difference of a few K didn't matter.

It began to matter when noise temperatures started to tumble to as low
as a few K. In order to avoid significant measurement errors, the
reference temperature T0 now has to be defined separately from the
physical temperature of the noise source, so that the difference between
the two can be allowed for.

>but unless the Ham fraternity
>wish to break away from the accepted standards anything which is
>discussed here is unlikely to influence

>the convention.

I don't know where you get the idea that "the ham fraternity wishes to break away from accepted standards". I am in very direct contact with that segment of the ham fraternity that needs to think about noise temperature: everybody accepts the definition that 290K is a reference temperature, unconnected with ambient temperature.

Well, Dick, I've already said what I'm going to do about it directly (since I have no interest in HF right now, I'm going to do nothing). However, in the context of what you said above, I don't like pastrami, so that's out. But I do expect to enjoy the radio capabilities I have, barbeque steaks on the grill, enjoy the coming summer, and hope the rain goes away so I can sit around on my boat and soak up some harmful UV rays. In addition, I intend to address this topic occassionally when it comes up in this newsgroup.

If you constructed the J-Pole correctly, and found the correct feed point, you should not nave any problems with coupling.

HOWEVER:

VHF J-poles do have a tendency to radiate the coax ! This may be wheat your experiencing. Get a dozen or so tight fitting ferrite beads and slide them on up near the feed point and see how this works !

Sorry, I hit the send button before responding to this. Anyway, unless your name is Bill, I wasn't trying to "sell" you on anything. And, since you want to be so huffy about this, let me add that I was also one of those who cared enough to do it - when I was about thirteen in the Boy Scouts. Since then, I grew out of flashing messages with my Boy Scout flashlight and beeping messages to kids on the playground with my little decoder ring. Since then, I learned the best way to communicate is to talk, and I have used my knowledge about radio to improve my station enough to do that effectively without having to resort to an 18th century telegraph key. Perhaps you should learn more about radio so you can do the same. :-)

5724. Re: G5RV question?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-24 11:59:19 UTC
From: jhilins <jhilins@bellsouth.net>
Message-ID: <3ABC8C15.12FAB8F3@bellsouth.net>
Source record: 167698

SCRAP the G5RV !
Here's how to make a better antenna from the same material.

First of all a G5RV needs a antenna tuner to work !

Here's how to build a better antenna.

Start with 200' of wire and at least 50' of latter line (More the better)
cut the wire in half and attach each half to the ladder line to make a dipole. (use a center insulator for strength)
Get the center point up as high as possible, run the wires to the two trees you have get the ends up as high as possible. (Use masts in the trees if necessary)
If you can continue through the trees, bend the wire if possible and terminate without cutting, if you can't bend 90 at the tree and bring the wire down until it almost touches the ground. Cut if necessary.

Now the ladder line must drop vertically from the wire, use as long a run as possible. If possible bring the ladder line into the shack and connect directly to your tuner.

A lot of people don't like bringing ladder line into the shack. If this is true with you, then bring the ladder line to a point just out side the shack, get a 4:1 balun and transition to coax (Use nothing lower grade than 100% shielded RG8, preferable RG213 or LMR400.

It is helpful to add 12 to 15 ferrite beads to the coax get them up close to the balun.

Bring the coax or ladder line in and connect directly to your tuner. I use a configuration close to this except I off center feed it, it will load up on all bands 160M-6M using only the internal antenna tuner built into my IC-756.

The key here is
#1 height (Use trees and poles in the trees if necessary)
#2 wire length longer is better (Don't be afraid to bend it but high ant straight is better)
#3 use a long piece of ladder line it will become part of the antenna on lower freqs (Keep it a vertical drop from the antenna, and don't allow it to parallel the antenna)

You will start noticing significant gain starting ton 40M-and a huge sig on 6M. (Caution 6M will be directional off the ends of the antenna!)

Source record: 167699

Bruno,
For a temporary antenna a dipole should work just fine.
They're pretty versitle as to how you put them up, so you
may find that it may be just what you need. The cost of
making a dipole just depends on what you may have in the
junk-box. Definitely cheaper than a beam!

In reviewing Friis's original article on noise figure in the Proceedings of IRE, I did not see a specific temperature mentioned. However, an IRE standards committee, headed by Prof Haus at MIT, recommended a standard lab temperature of 290K.

The ARRL Handbook, 1995-2001, chapter 17, (just as one example, there are others) discusses a more generalized noise factor that is not pegged to a specific temperature. It is referred to as a "system" noise factor Fs, where the system includes the noise temperature of the antenna and the equipment temperature (indoors and outdoors). The Friis-like formula for total system noise temperature takes into account the temperature of every element of the system, including W8JI's liquid nitrogen front end for his 160M Beverage antenna.

If we use this method, a typical receiver at 2 MHz would have a system Fs less than 1 dB, which means that nothing that we do the receiver itself can make a difference. But at 10 GHz the same receiver noise figure would obviously be very important.

"Hi Bill,

We have to be careful or we will perpetuate the myth that "magnetic" signals in a shielded loop pass right through the shield, while "electric" signals are shorted. That isn`t true at all, and it is easy to prove.

The "shield" does not change the field impedance of the loop at all. It does not sort the "magnetic" part of the EM wave from the "electric" part of an EM wave. It does not sort signals from noise.

All it does is modify the balance of the structure, and improve balance if it is installed correctly.

73 Tom"

The shield on a loop is a Faraday shield and it does what all Faraday shields do, and that is no myth. It does exactly what Tom says it does not do. Well, Tom may have the "field impedance" right. I haven`t checked, but any antenna that extracts energy from a passing wave affects the field. The shield may not perturb the passing wave any more or less than the loop without the shield. But that isn`t the dispute.

Best regards, Richard Harrison, KB5WZI

<xcg34@dial.pipex.com> wrote:

>
>What do you make the sky temperature at 1.75 MHz?

No, unfortunately I did it on 1.83 MHz or so.

Naturally, it is quietest at mid-day.

Using 3.5 kHz bandwidth, noise floor was -123 dBm (with no feedline
loss) in my 75 ohm system on a winter night when the band was wide
open to Europe. The antenna was pointed NE with a HPBW of about 40
degrees, and is about 1% or so efficient.

>What is the measured efficiency of the Antenna that you use to measure the
>sky temperature.

We've been through that. Since my vertical is close to 100% efficient
(a 200ft tower with 100 200 ft long radials) it's easy to verify the
signal levels of the receiving antenna.

>I'm afraid that your quotation of the signal level in a bandwidth without
>some qualification is not prima facie evidence of sky temperature.

Neither is you math, especially when real-world measurements and text
on noise levels at HF disagree with your "results".

>> How dare you imply that a "large number" of Hams are lazy.
>
>I do not imply, I accuse,
> just listen to the rubbish that is exchanged on air.

OK, so you think Hams "talk trash".

>I attempted to give a short talk to a group of about fifty Hams, it was all

Source record: 167707

I'm picturing a Larsen cartoon entitled "When good traps go bad" :o)
I used to have an older Cushcraft A3S. I eventually replaced both
pairs of traps in the driven element. This definitely improved things,
as the SWR came down noticeably. Some have complained of poor
service from Cushcraft- I can report that the person I spoke with was
both knowledgeable and quite helpful. This was in the mid-90s.

A couple of interesting details about traps in tribanders:
You can test them by running the driven element in isolation,
i.e. removed from the rest of the antenna (in the case of the TH-7
etc. this test would be run twice, once for each of the two elements)
In isolation, the DE should have a 'low' SWR. It is pretty much that
simple. Of course, you do have to make sure the resonances are
where they belong. Bad traps will display an obviously high SWR
at resonance. Usually the only option is to either rebuild (difficult)
or replace each bad trap (best IMO). You do need to have the
element under test up off the ground a ways, but probably 6-10
feet would suffice for 20 meters up. Resonance will move a bit
lower than that at full height.
Another interesting detail- traps in the reflector or director
elements rarely go bad. The reason is, the RF current is much
higher in the DE than the induced currents in parasitic elements.
This means, in turn, that the peak RF voltages between the coil
winding and ground (the metal case of the trap) are lower in
parasitic element traps, so they are less likely to break down.

Here is how they 'go bad': Not only do spiders build nests in traps,
but here on the US east coast we have a tiny native wasp that
apparently is very fond of hiding places with small circular
openings- like the weep holes in traps. These little critters drag
grass clippings up in there. I would not have believed this story
before I learned how to service traps, but when I opened my
bad traps, there were the grass clippings. Here's what happens:
when it rains, water gets sucked up into the trap by capillary
action. You end up with a sodden mass of stuff in the bottom
of the trap. At high power, sufficient RF voltage can develop that
you start getting little arcs from the coil winding to ground. Over
time, the coil wires lose their insulation and develop little burnt
spots. These are invariably found only along the bottom of the
coil. Some can approach the size of a coin when they get
really bad. So if you have DE traps that fail the SWR test, open
them up and look for any burnt spots. Look very carefully, as
they can also be small. Replace any bad DE traps and you
should be back to normal, so long as there are no other
electrical problems in the antenna. (Another problem that

shows up is intermittant opens in traps, caused by aluminum
coil wires that 'cold flow' under the pressure of a screw heads
compression) If the antenna is old enough that the DE traps are
going bad, it is a good idea to service (open and clean) all
parasitic element traps as well- but they would likely not fail
the SWR tests (try it). Reflector resonances should probably
be 3-5 percent lower frequency at resonance, directors 3-5
percent high.
BTW I can't tell you the exact failure mechanism, i.e. why the
coils with the burnt spots should be 'bad', but the before and
after SWR tests make all obvious. In my traps, the winding was
spaced out as I remember, so I can't see why the removal of
enamel insulation should be so detrimental. But it is. I guess
the coil Qs go way down. Heck, traps are lossy enough anyway
and represent compromise and tradeoff in antenna design.
They need to be in good shape. It's hard to beat monobanders
if you have the space for them. 73, David K3KY

There is a wise saying: "When you look into the abyss, the abyss looks back at you". Kafka?

This applies to receiving antennas. When a wave couples a signal into the antenna, it couples some of that signal back into the space near the antenna. This can modify the Z0 impedance near the antenna. Roy's very nice work on the impedances vs distance is a good example. The rod antenna' s voltage reflects an E field (lower Z0), the loop antenna's current reflects an H field (higher Z0).

Ya have to also remeber to take into account the location. I know up here
having a coil/tap setup would be awful on those icy/snowy days as it will
short the coil quite nicely.

No one is getting huffy but I do have a certain difficulty calling a
manure pile a 'fertilizer storage facility'. New does not imply good, old
does not imply bad. All things in context.

The context here is a lot of breast beating self-justification for not
taking the code test. We can talk coulda, shoulda, hafta from now til
Independence Day but the cosmic interplay of choice and chance has made it
a requirement to do 5wpm in the easiest manner possible for at least the
next five years.

What you choose to do about it if anything is purely up to you. You don't have to justify it to me or anyone else. If it is a self-worth issue, it is YOUR self-worth issue. So stop with the justifications already. It is not about the mode, it is not about VHF-UHF vs HF, it is about a code test that is more of an inconvenience than a hurdle for most people. Obfuscation merely irritates.

It is particularly irritating when the audience is composed of people who, for whatever reason and by whatever method, passed a code test. There is a time and place to call golf a stupid game -- the gallery at the Masters is more than likely not that time or place. Preaching the Gospel on the road between Mecca and Medina is not the best context either. So why in hell are you doing it?

[snip]

Ha... just as I suspected. Richard, please check your dictionary [Webster or Oxford is fine] for the meaning of "fiction".

So that's it. You believe that Dissipationless Resistance is a "fictional resistance". Of course! Why didn't I think of that?

Fiction is better than reality any time. In fiction one does not have to obey the Laws of either Man or Physics.

Of course "radiation resistance" is a real resistance since it is certainly not "fictional".

Richard, sometimes I feel that the proponents of "dissipationless resistance" are actually doing "Science Fiction"!

Except this is not a court scenario...nor is the FCC arena
when it asks for or otherwise accepts comments on rules.
One need only examine the use and role morse code now plays
in any communications service to see it is significantly
diminished in need. The value of code to an individual
on a personal enjoyment basis is not the rational the
FCC uses in determining value or need.

Additionally, as a counter-point to your court "expert-witness"
scenario, you must admit that in the end, it is the jury
of people that do not possess that expertise that
makes the decision.

By the way, it doesn't take that much effort to be deemed an expert witness in most cases. The opposition will use its crossexamination time to discredit any expert witness...but in the end it goes to the jury for the final choice.

Cheers,
Bill K2UNK

I agree. I have never suggested that code,, as a mode, not
be included in the overall knowledge base.

> they choose to do so.

That's not the implication at all. This ain't rocket science. Hams who want to use Morse code learn it and use it. Hams who don't want to use Morse code don't learn it or don't use it and forget it. Hams are hams whether they know and/or use Morse code or not. I know quite a few hams who learned Morse code and NEVER used it at all. They simply didn't like it.

There were many thousands of early Technicians who passed a General written exam and a 5wpm code test who never copied a single character of code after that. They were issued 1x3 calls starting with a 'W'. In those days, you couldn't tell a Tech from a General by knowing his call. Everyone with an amateur radio license was a ham.

According to the ARRL survey, a majority of hams use CW "rarely or never". Would you say a majority of hams are not "real hams"? I got news for you. "The Amateur's Code" doesn't mean Morse code. What is wrong with live and let live?

It's the Mandatory Higher Speed Morse Horse that is dead and gone.
But some "real hams" will administer CPR until that horse's lips
rot and fall off.

Did you know that Roy Rogers wanted to have himself stuffed and
mounted on Trigger but it's illegal to do that to humans?

I don't have the original papers, but had understood that Friis did
suggest a reference temperature of 290K in his original 1944 paper, and
that the IRE's contribution in 1959 was to adopt it as a standard.

>The ARRL Handbook, 1995-2001, chapter 17, (just as one example, there are
>others) discusses a more generalized noise factor that is not pegged to a
>specific temperature. It is referred to as a "system" noise factor Fs,

There's a fundamental problem with the concept of including antenna
noise into a "system noise factor", namely that an antenna does not
really possess a noise factor (or figure) - it only has a noise
temperature.

AFAIK, the current basic definition of noise factor remains as
(signal/noise ratio at output) / (signal/noise ratio at input).
This definition is clearly limited to devices that have both an input
and an output, which excludes one-port devices such as antennas and
laboratory noise heads. The 1959 IRE standard is actually entitled
"Noise in Linear Twoports".

The formula for the noise factor F12 of two cascaded stages is:

F12 = F1 + (F2 - 1)/G1

If the first stage is an antenna and the second stage is a receiver,
the formula can only be made to work by treating the antenna or noise
head as if it were a two-port with a gain of 1. This Friis "like"
approach works in a limited way, but it does not stand up to much
questioning. (Does an antenna have an input S/N ratio? Does a noise
head?)

On the other hand, antenna and receiver noise temperatures simply add
together. It's completely rigorous (unless you're into low-noise
millimetre-wave and photonic devices, where quantum effects become
important). In practical engineering terms, that means it's a concept
that won't ever let you down.

>where
>the system includes the noise temperature of the antenna and the equipment

You have (accidentally?) stumbled upon a length of feedline that presents
a decent load to your built-in auto tuner. Many have stumbled upon lengths
of feedline that don't work with built-in autotuners. For anyone wishing
to get serious about this subject, I recommend downloading the free demo
version of EZNEC from www.eznec.com. The length of the feedline can make
all the difference in the success or failure of a ladder-line fed dipole.
More information available on my web page.

After looking around for antennas, I've looked at rotatable dipole. Is this worth spending the money for the antenna and the rotor ????

I know that the rotor could always be reused for futur use and other antennas so it's not totally lost, but for the cost of antenna, is it really worth it ????

Thanks again

Specifically, they can only make their determination by weighing the evidence presented during the trial. They are not allowed to consider any personal opinion or facts other than what has been admitted as evidence in determining guilt or innocence.

> By the way, it doesn't take that much effort to be deemed
> an expert witness in most cases.

True, you just have to show the court that you have the experience and expertise of the subject necessary to validate your opinions, and therefore allow them to be admitted as evidence.

> The opposition will use its crossexamination time to discredit any expert
> witness...

They will try... But this is how the game is played. Nevertheless, the court will recognize a person as an expert witness based on their qualifications. If they are qualified to testify as an expert witness, their opinions will be entered into the case as evidence. The jury will never be allowed to hear a layperson's opinions.

>but in the end it goes to the jury for the final choice.

Again, to be based solely upon the evidence presented during the trial, not their personal opinion or feelings on the subject.

Hi Gary,

I really don't know if they were so equipped (this was only 28 years ago) and all I can report is what appeared on the 'scope. I didn't step out to look because my station was at that radar, and anyway, it was raining.

As my ship was 600 feet long displacing 25,000 tons, we had a long braking distance. The fleet on the other hand could easily look out after themselves (but would undoubtedly bring a grumble about missing their catch). They weren't entire low tech, as several switched on their own radars when we appeared, my radar began to fill with fine filigreed lines of their own sweeps mixing with mine.

We had been running ahead of schedule, so the old man headed us out to sea (out of the lanes) to kill time. The watches for several days were nothing but boring. This episode on the dog-watch at least gave us a break (and kept the look-outs awake). On an Atlantic crossing, my buddy (AA7UJ) sat at the radar with a split set of sound powered phones to the watches as the rest of the crew dozed (about 6 people in CIC). The XO popped his head in, shook it, and closed the door carefully so as to not waken the fellows. My ship was not what would be called a warrior. We qualified only to the extent of maintaining a 40mm cannon so that we could keep our warship status (and thus escape certain dockage fees and excise tax). On the other hand, in my lab, I was never more than 20 feet away from a Polaris missile with its atomic payload - and perhaps a dozen more like it nearby.

Some might wonder about the laxity of the XO. After all, we did carry a considerable amount of classified information and would be a prize vessel if captured. No, the XO knew we had a submarine escort for just this possibility - the sub would have sunk us long before we would've been boarded. :-)

I did not say "antenna noise factor". I said "antenna noise temperature". I just took a look, and that is what I said.

> The formula for the noise factor F12 of two cascaded stages is:
>
> F12 = F1 + (F2 - 1)/G1

I did not say this formula. I mentioned the formula for cascaded noise temperatures. Not the same thing. I said "Friis-like" not "Friis". Not exactly the same, but somewhat similar. I have just verified that also.

> On the other hand, antenna and receiver noise temperatures simply add
> together. It's completely rigorous (unless you're into low-noise
> millimetre-wave and photonic devices, where quantum effects become
> important). In practical engineering terms, that means it's a concept
> that won't ever let you down.

This is not 100% true. The ensemble of temperatures in the complete system do not just "add together". Gain (or attenuation) values are involved. The formula that I am talking about is in many handbooks, including on page 17.38 of the ARRL Handbook. That material was written by me, and it has been verified to be correct. See also ARRL UHF/Microwave Experimenter's Handbook.

When the system temperature is figured, the Fs system noise factor is the ratio of system temperature to antenna noise temperature. By the way, I did not invent this idea myself.

Page 17.38 works out an example. Suggest you refer to it. If you do not have an ARRL Handbook I can scan the pages and email them. I will be pleased to do that.

"Ha...just as I suspected." (check the dictionary for fiction`s meaning)

I apologize for unauthorized use of a pedantic term, "fictional resistance", as I am no pedagogue. I don`t even play one on TV. I`ve often seen radiation resistance explained as a fiction which replaces the voltage to current ratio of the radiated energy from an antenna. The radiation resistance is dissipationless because it doesn`t heat up the immediate vicinity. But, it is real.

"Fictional" was ill advised, and I was my own advisor. Shame on me!

Best regards, Richard Harrison, KB5WZI

Hello, Jim

The OSJ (Open Stub J-Pole) is end fed.

With proper construction, the OSJ has NO problem with radiating the coax,
or the mast. This is what I am trying to get through to people.

Sorry, Bill, I wasn't making my point clearly enough.

The point I had been trying to make (and not very well, I admit) was that if you combine the antenna with the receiver, and call it the "system", then the whole system becomes a one-port device, to which the concept of noise factor does not properly apply.

You are right that I got confused, although not about the reason. On looking more carefully at the examples in the ARRL Handbook, it turns out that the so-called "system noise factor" (a) is not a standard form of noise factor, and (b) does not apply to the whole system, only to the receiver!

To demonstrate (a) and (b), let us temporarily simplify the "system" to just two stages, the RX and the antenna. If there are any losses between the RX and the antenna, they can be absorbed into either Tant or Trx with appropriate corrections (which are not in dispute).

If Fs is defined as (Tsys/Tant), and Tsys has been simplified to (Trx + Tant) then:

Fs = (Trx + Tant)/Tant = Trx/Tant + 1

This does indeed have the form of a "noise factor" equation (compare with the standard equation, Frx = Trx/T0 + 1) but it is actually a non-standard representation of the *receiver* noise factor, referenced to Tant instead of T0.

If we now re-introduce losses between the receiver input socket and the antenna, it makes my point less easy to see, but I don't believe that affects its validity.

There are obvious uses for the ratio (Tsys/Tant) or (Trx/Tant) in system design - that's not in dispute. The whole problem lies in the misleading choice of name.

I appreciate that you didn't invent the term "system noise factor", and
am not blaming you for its existence, but the name is highly confusing
when it's neither a standard noise factor nor truly belongs to the
system.

Well, I for one was highly confused...

> matter who says it or how many times.

Notice that the capacitive coupling which has been suppressed by the
grounded shield was the result of an electric field orientated in a

direction roughly perpendicular to the shield.

The electric field associated with the time varying magnetic 'coupling' field is orientated in a direction which tends to induce circulating currents in the surface of the shield. These currents are perpendicular to the capacitive 'displacement' currents described earlier. Introducing a narrow slit in the shield will interrupt the currents circulating on the surface of the shield but can be arranged to have only a negligible effect on the shielding effectiveness to the capacitive currents. The EMF generated by the time varying magnetic field penetrating the conductive shield will establish an electric field across the the slit. The geometry of the slit is chosen so that the electric field which exists in the vicinity of the slit does not create additional undesirable coupling modes.

The Faraday shield was able to suppress coupling from electric fields generated by common mode voltages between the primary and secondary windings. The Faraday shield did _not_ suppress the circulating electric field associated with the time varying magnetic field responsible for the mutual inductance between the windings. It was possible to suppress coupling due to one electric field component from another by exploiting the different orientations of the two components.

> the other regenerates its partner.

No we can't. Maxwell's equations succinctly state that you cannot have a time varying electric field without an associated time varying magnetic field. T'aint no way.

> We short and open transmission lines,
> don`t we?

A good thought experiment is to visualize what happens to the electric and magnetic fields when a transmission line is opened or shorted. Both electric and magnetic fields continue to exist. The arrangement is different but they still satisfy Maxwell's equations and the imposed constraints (boundary conditions).

> An antenna can be equipped with a Faraday screen to block an electric
> field while allowing magnetic fierld excitation, just as happens with
> the Faraday shielded coil.

The Faraday shield suppresses the coupling between the antenna terminals and a particular electric field orientation. It does not block all electric field orientations, otherwise the antenna would not work.

Cecil:

Yup... I'm sure it will. But there is still hope of re-directing the use of that unfortunate description by steady misuse.

Dissipationless Resistance will never go away now, but maybe with sufficient misuse we can all get it "outa here".

My idea is that the denziens of this newsgroup should "trick" some special interest group into adopting "dissipationless resistance", sort of like those who adopted that grand old word "gay", and then encourage them to overuse it.

Then after a while the whole meaning of "dissipationless resistance" will change and we'll be back where we need to be with plain old radiation resistance, surge resistance, ordinary resistance, etc...

Hmmmm.... now what special interest group could we con into this....

Eureka! I know... let's get the proponents of "fractal electromagnetics" to adopt "dissipationless resistance". They will then use it all over the 'net, and in no time at all we will be free of that dammed "fiction". Fractal antennas all have dissipationless resistance!

All other suggestions are welcome.

Best Regards,

-Peter K1PO ["Fractal antennas have dissipationless resistance!"]

Jim if your jeep is a CJ type you roof isn't metal so you are going to have a ground plane issue. I have a '86 Wrangler and have a TH70 in it. I installed a ball mount on the back 1/4 panel with a Perth outback.... I couldn't get a match no matter what I did. Then I found out that the out back can not be next to any vertical metal. i.e.. the roll bar and struts for the soft top. I replaced the antenna with a hustler that have the coil that you put on top of a 54 inch shaft. Now it works GREAT. The only thing is that you have to replace the coil to change bands. They do make a plate that will hold 3 coils at a time, but there was too much wind load on it. The HF works great in the jeep, other then 10m and 11 m. Some place it is getting rf into the car computer and shuts off the motor when I key up. I have even used a 1/4 wave whip on 10 and it still does the same thing..(so not the fault of the hustler.)

Hope that this helps

The term F does not apply, but the term Fs does apply. It is the ratio of total system noise temperature to the noise temperature of the antenna alone. This is very closely related to F but it is not measured with everything at 290K. If everything is at 290 K, including the signal generator noise temperature, then F and Fs are identical numbers.

I don't agree, and quite a few others don't agree, that the term is "useless". I put a lot of thought and literature search into the Handbook writeup, and I like it. The reason I like it is that it puts the receiver into perspective vis a vis the rest of the system, parts of which may be at widely different temperatures.

Being a EME guy etc, I suggest you think about it some more. It is nifty, in my opinion.

Also, the Friis formula has to be used carefully, or it is easy to get wrong answers, especially when attenuation (eg filter loss) between active stages are involved. I have been down that road. The temperature formula has to be approached with the same caution. If we are not careful we may get an answer that is close to right, but we are not using the correct method.

I have found that it is best to adhere to both of those formulas and not make assumptions. One of the contributors, and also my co-editor, to HF Radio Systems and Circuits fell into that trap and I had to bail them out.

Part (b) is definitely not true. Fs refers to the *entire* system, from some faraway galaxy to the loudspeaker. It is one of the standard forms that a lot of people recognize. It is perfectly valid.

> To demonstrate (a) and (b), let us temporarily simplify the "system" to

But if there is loss between amplifier stages, we may have to use the complete equation 8 on page 17.38 if we intend to use the correct procedure, and not some approximate method that may give a close answer but is not a correct answer that is good enough to put into a text book.

I think I have stated my position clearly. It's what I am satisfied with, and I don't say that casually. I have been down the road on this subject over many years.

Best regards, Ian, and thanks for your comments about the EM topics. That is one tough, tough subject to get a good handle on and I keep struggling with it. I am convinced that it is tough also for a lot of others who have "definite" ideas that do not always pan out. I am still not satisfied with the discussions about reflection. At radio frequencies a resonant plate is a much better reflector than some arbitrary dimension.

> Bill W0IYH

At radio frequencies, especially HF, a non-resonant reflector can have a lot of radiation off the *back* side of the plate. I believe this agrees with Maxwell's equations OK because it maximizes energy available for reflection. A perfect standing wave on the plate is better than anything else.

Source record: 167596

There's no need to depend on accidents to discover suitable lengths
of feedline for any dipole at any frequency on any band.

Use program VARNEY.exe to search systematically, sweeping through
length or frequency for suitable input impedances.

Download program from website below, not zipped up, run
immediately. Enter antenna details and feedline impedances, coax or
ladder line or both together, and obtain accurate answers in
minutes.

If in practice you obtain Tx load impedances different from
predicted values then it's due to such things as your 450-ohm
ladder line being something different from 450 ohms. The program
enables you easily to check the dependence of input impedance on
the impedance of feedlines. L and C component values of an L-match
to 50 ohms are automatically included with all results.

The foregoing uses of the program are by-products. The distribution
of losses between coax, twin feeder, antenna and ground is obtained
immediately. An N-to-1 or choke balun between coax and twin feeder
is allowed for.

But in summary, this program will show that for multiband use the
G5RV offers no advantages over any other random length, center-fed,
HF dipole. With the coax it is worse than most.

If it is very lossy/ inefficient, I think that it does. Not that it is a very useful thing for any further calculations such as communication matgins etc..

The form (So/No)/Si/Ni) is modified because No = Ni x Loss + Tambient(1-Loss)

The fact that the inefficiency of teh antenna modiifies (So/No)/Si/Ni) to (So/No)/Si/(Ni Loss + Tamb(1-Loss)), is identical in form to what happens as we progress through and amplifier or receiver.
Still noise factor really doesn't progress things very much except as an evaluation of the receiver. The value that we really require is Ts = Ta + Tr such that we can examine the threshold value for any communications mode. It is the Ts that we have to work with in the practical case, it is this value that we are unable to modify. Attempting to measure Tr is a fairly futile exercise and as it can not be seperated in practice we run with Ts.

> On the other hand, antenna and receiver noise temperatures simply add
> together. It's completely rigorous (unless you're into low-noise
> millimetre-wave and photonic devices, where quantum effects become
> important). In practical engineering terms, that means it's a concept
> that won't ever let you down.

Providing you use well conditioned equations for the calculations.

I have found this one particularly stable when using the hot cold load technique for measuring Ts.

Ts = (To -Tn)/ Yna(Yon-1)
Where To is a load at ambient temperature
Tn is a load immersed in Liquid Nitrogen and the actual noise temperature is determined from the insertion loss of the load to the actual switching point between loads.

Yna is the ratio of detected noise power outp of the system whenthe input is terminated in a load Tn and then into the antenna that is to be used for comminication.
Yon is a similar ratio between noise power out of the system when terminated in a load at ambient temperature and a load at liquid nitrogen temperature respectively.
In practice the liquid nitrogen effective noise temperature works out at around 83°K allowwing for the losses in the connector and short length of line from the Dewar to the receiver input measureda at 0.01 dB and this bit of line is at ambient temperature.
Of course the formula is valid for any other hot /cold load temperatures.
The main difficulty is to ensure that the temperature difference between the hot and cold load is sufficient to give reasonable measuring accuracy at the systemp temperature of the system under measurement.

If an expert witness testified the sky isn't blue, would they
be required to accept that as fact? The reality is that
the jury gets to make their own determination as to the

accuracy of whatever they hear is. They do not automatically accept everything as fact.

Rhetorical question Reg, the noise temperature of my source is a little higher than usual as Tom has a blow lamp directed at my arse.

BTW do you know a surgeon that will remove tongue deeply embedded into cheek for a special price?

To be serious for a moment as I know that you have done a loot of serious work on Antennas I am very interested to know why you have never considered measuring the efficiency of any of your antennae. VSWR is OK for match etc., but the determining factor for the quality of any antenna is most surely its efficiency.

> open to Europe.

OK thank you Tom
noise into Rx = -123 dBm
3,500 Hz is 35.4 dBHz

k = -198.6 dBm/Hz/°K

-123 dBm = -198.6 + 35.4 + ? dB°K

Which give 40 dB for the noise temperature delivered to the Receiver.
Which is 10,374°K

> The antenna was pointed NE with a HPBW of about 40
> degrees, and is about 1% or so efficient.

Temperature into the antenna = 10,374 x 100 = 1,037,366°K

Allowing that you are collecting noise from 40° of the sky it might be easy
to jump to the conclusion that this factor 360/40 = 9 brings the value for
sky temperature to aproximately 9,000,000°K that I originaly claimed.

However I am not sure that this is what infact happens, because we should be
considering a two dimensional angle and insufficient data is available to
complete the final step of that calculation. Never the less we can see that
we have ball park figures.

> >What is the measured efficiency of the Antenna that you use to measure
the

I would like to know how you calibrated the efficiency of this antenna as
you use it as a reference.

> (a 200ft tower with 100 200 ft long radials) it's easy to verify the
> signal levels of the receiving antenna.

I wonder what sky temperature you would get if you measure it through the
vertical.

With sufficient different antennae we should have enough data to solve the
simultaneaous equations and resolve the actual sky temperature; and from
that calibrate each individual antenna for efficiency.

If a daily published value for sky temperature is made available then any
Ham can calibrate his antenna efficiency with a simple measurement.
Perhaps hourly values for sky temperature could be made available.
The calculation can be performed retrospectively when the measured
temperature becomes available.

So long as any measurements are only to be used by a single station to evaluate its own performance ther is no difficulty you may use and understand what is convenient to that station and there should be closure withing the closed measuring system. The diffuclties only occur when a station wishes to perform a calibration in conjunct with some other station or stations then an agreed standard is mandatory if the results are to be meaningful. Providing such a standard is probably still the perogative of the National institutions.

Quite so and for low HF they still don't because of the very high noise environment at the low frequency end of the spectrum. Assuming that efficient antennas are used.

> It began to matter when noise temperatures started to tumble to as low
> as a few K. In order to avoid significant measurement errors, the
> reference temperature T0 now has to be defined separately from the
> physical temperature of the noise source, so that the difference between
> the two can be allowed for.

Indeed it was ever so in the 1960. We had an accurate digital thermometer permanently strapped to out load at ambient temperture used for the calibration of system temperature about six times a day. a slight correction

of the To-Tn value was made from the digital thermometer reading in practice
we are speaking of a difference of To from 20&#65533;C to 27&#65533;C
Thus (300-83)/(293-83) gives about 0.14 dB difference in the reference
values.
In reality this probaly altered the measured value for Ts around 40&#65533;K by as
much as a degree or so. Cetainl on a very long bit error test the increased
errors could be counted, our specification was less than one character error
per thousand cahracters, so we were well within the required specifications
and the science team were content with the data so provided. This is errors
in the decomutated instrument data not the precision of the onboard
spacecraft instrumentation. Each instrument had its own spec but the
communication system was capable of faithfully relaying the collected data.
That indeed is exactly the same requirement that the Ham places upon his
equipment whether that has been formally identified or not.

> >but unless the Ham fraternity

Please note the qualifying word "UNLESS" it makes all the difference to the
meaning of my statement.

>I am in very direct contact with
> that segment of the ham fraternity that needs to think about noise
> temperature: everybody accepts the definition that 290K is a reference
> temperature, unconnected with ambient temperature.

Valid when Noise figure is measured by sophisticated laboratory
instrumentation, but not so when more fundemental methods using hot and cold
loads are employed.

Presumably you are familiar with the Dicke Radiometer?

Something funny here...

I got on a web engine and found this url

http://www.ewh.ieee.org/soc/aps/2001/advanced/advanced_full.htm

It lists all the papers for the fractal antenna session on Wednesday. You know,
the one Stephen best refers to. There are NO TALKS listed by one Stephen Best.

Again there are NO TALKS listed by one Stephen Best.

Check it out.

Maybe he spoke too soon?? Or....maybe it's not true??

What's even more curious is there IS a talk by Dr. Cohen which sounds like it's
on the same subject as the second talk Stephen Best says he's giving.

It's all so surprising!

The description "fictional" or "imaginary" resistance is correct in some antenna situations.

Radiation resistance should always be referenced to a particular point in the antenna. In the case of a short vertical it is often referenced by amateurs to the base feedpoint where it then becomes equal to the feedpoint resistance. This causes misunderstandings. It is strictly incorrect to describe the feedpoint resistance as radiation resistance. This is true only when an antenna is fed at an antinode. The handbooks and magazines written parrot-fashion by plagiarists are in need of correction.

To avoid ambiguity, unless otherwise stated, radiation resistance should always be referred to a current anti-node (a current maximum). This is the place to where Terman, Everitt, to name but two, made reference. In the case of a half-wave dipole the radiation resistance of 73 ohms is then referenced to the centre whether it is fed at the centre or not.

And in the case of a quarterwave vertical the current antinode occurs at the base of the antenna. All is well and the feedpoint resistance is equal to the radiation resistance of 36 ohms.

But when the vertical is shorter than a quarterwave there IS no current antinode. Nevertheless the radiation resistance is still referenced to that fictional or imaginary point which would exist if the antenna had been long enough to have one. And so the radiation resistance itself is fictional or imaginary. Nevertheless it is real enough to be assigned a value which can be used in efficiency calculations, etc.

The ancients did not dream up these imaginary resistances just to make things awkward for succeeding generations. They come about in a perfectly natural manner when radiation resistances are calculated from first principles by summing the contributions of each small element beginning with a standard current of one ampere at an antinode. If the antenna is shorter than 1/4-wavelength then the summation does not begin until the antenna starts. But the reference to 1 ampere at the imaginary antinode remains for all time.

The length of wire between the feedpoint and nearest antinode, imaginary or not, behaves as the necessary impedance transformer.

That this is not a trivial matter can be judged from the fact that the radiation resistance of a short antenna increases as the 4th

power of frequency but the feedpoint resistance increases only as
frequency squared.

A lesson in how to lie without really doing it- the talks are by "Steven Best", not "Stephen Best", and there is no listed talk by Cohen, at least in the Wednesday morning session, which is where the Fractal stuff is listed.

He told the truth about "Stephen", but made an implied lie about "Steven".

The Idiots are still with us.

Bruno,
That's a subjective question, and I don't know how to
answer it for you. There is a difference in what you
hear/don't hear with a rotating dipole. If that difference
is big enough to be worth the cost is up to you (and your
wallet). If your only looking for a temporary antenna
until you get your new one, I'd think a rotating dipole
might be a bit too costly (for me, anyway). If you already
have a rotor, tower/pole, etc, then it may ~not~ be too
expensive. What would you do with it when the new antenna
get in?
'Doc

Not specifically. Just make sure you use a good braided ground strap
from the chassis directly to ground and wire the power directly to the
battery and you should be ok.

Bart, WB6HQK wrote:
"No we can`t." (kill one constituent of a radio wave without killing the other)

I am aware that Maxwell says:
1) When an electric field changes, it creates an magnetic field.
and:
2) When a magnetic field changes, it creates an electric field.

Perhaps I should have said: You can short the electric field without killing the magnetic field.

My recollection is that a short on a transmission line forces the electric field to zero at the short, and it also forces a reversal of electric field polarity as it is changing the direction of travel. Also, the forward and reflected voltages must add to zero. In very short time and travel, strength of the electric field is restored. The current direction is unchanged as it just makes a U-turn sooner due to the shorted line, but doesn`t really change direction. Also only the voltage or the current changes polarity, not both constituents of the wave, at a reflection point.

My recollection is that energy is conserved when either the electric field is forced to zero (at a short circuit) or the magnetic field is forced to zero (at an open circuit) by a very temporary transfer of all the energy, it amounts to a double, to the surviving field. The subsequent energy redistribution to a 50-50 split is very rapid.

It`s been almost 50 years since I had to work with Maxwell`s equations. I`m lazy and loath to take them up again. Also, I think few readers would be interested in following the reformulations anyway.

Best regards, Richard Harrison, KB5WZI

I don't want to rid ham radio of CW, Dick. Each and every one of those
digital communications experts understands the usefulness and utility
of CW, whether they use the mode or not. I encourage all hams to learn
Morse code and try CW. It's fun for me and sometimes useful. What I
object to is the Morse code *requirement*, but you know that already.
You seem to think eliminating the Morse code requirement is the same
thing as ridding ham radio of CW. In that, you are simply delusional.

Hi
I have been wanting to run hf from my apt. here in London Ont. Canada for sometime and I have a Kenwood TS-440Sat. I ahve used it mobile but never in my apt. but now want to.

The problem is I am in a 7`th floor apt. with a balcony. What do I use for an antenna.

Also interference any tips on what to use. I used to have a Taylor filter but that was a long time ago . I have baluns and lots of 14 gauge wire. And I have a source of Hustler coils.

Any help would be greatly appreciated. Thanks in advanced.

Message-ID: <99jmj3lvj1@neptunium.btinternet.com>
Source record: 167611

NEW PROGRAM TOPHAT1.exe

TOP CAPACITANCE LOADING OF SHORT VERTICAL ANTENNAS

Loaded by any number, zero upwards, of uniformly-spaced radial rods or wires, of specified length and diameter, circled by a ring of wire. With only one radial you have an iverted-L. By entering a large number of wires the hat will have the same capacitance as a disk of close-mesh chicken wire.

Enter antenna height and diameter, frequency. Guidance provided on estimating ground loss resistance. A coil is always needed either at the antenna base or incorporated in an L-match. Coil Q is asked for.

The performance of a short top-loaded antenna is generally several dB better than a coil-loaded antenna of the same height with the coil fitted 2/3rds of the way up the antenna. With a largish top hat the antenna current is sufficiently uniform vs height for there to be little or no advantage gained by inserting a coil in the antenna. It can then be incorporated in the L-match or an automatic ATU and the antenna can be operated multi-band. With coil loading multiband working is not possible except with screwdriver-type antennas.

The superiority of capacitance loading is due to the smaller inductance needed to maintain resonance. If the coil has the same overall dimensions, and hence approximately the same Q, the coil loss resistance will be reduced for no increase in loss in the hat.

Sweep the principal input parameters over wide ranges using adjacent up/down keys on the keyboard while observing corresponding changes in radiating efficiency. The improvement in dB is calculated due to the hat compared with no hat.

Download TOPHAT1, 44 kilobytes, in a few seconds from website below.

The reference temperature of 290K is still needed. When commercial noise
heads are calibrated at a national standards lab such as NPL or NIST, it
is done in a constant-temperature chamber at a temperature of their
choice, somewhat above room temperature. However, the calibration data
are then corrected so that they appear to the end user as if the
calibration had been done at 290K.

That then leaves the user to apply a further correction for the actual
temperature of the noise source, once again to reference everything back
to 290K. It's awful hard to get away from.

BTW, the latest noise heads have a built-in temperature sensor right at
the output attenuator (which defines Tcold) and the noise figure
analyser reads and applies this automagically. With older noise sources,
there is a small error because you can only measure the temperature
outside the case, yet the source itself dissipates a significant
fraction of a watt, and thus has internal temperature gradients.

>Presumably you are familiar with the Dicke Radiometer?

Yes, although NPL now uses other techniques below 26.5GHz.

If you are going to use it on the higher HF bands, a simple whip is ok. On the lower bands, it will load, if you use a SGC-230 type tuner. If you try a cheaper tuner, such as a LDG, it probably won't. Too much inductance needed. Even if you do manage to match the whip, the radiation efficiency will be unacepptably low. Trust me: get a loaded whip of some sort. SGC uses one that has a self resonance point around 14 MHz. That loads from 80-10 meters. Jim

The most famous example is the radar "chaff" aluminum strips used to foil the Nazi radar. The lengths of the strips were carefully chosen to be resonant. If the strip is not resonant the wave passes right on through the strip.

Okay, using your own words, why are we treated to this self-serving observations on the obvious? I'm fairly certain all of us know the current state of affairs when it comes to the code test, so all that "coulda, shoulda, hafta," nonsense is just that.

> What you choose to do about it if

For the exact same reason that the person who passed the code test made the statements he did. And for the same reasons you made the statements you did. And both of those collection of statements were just as irritating when the audience is composed of people who, for whatever reason, have decided against the code test.

Why not mount them via the bumper ... You can get stainless steel whips in a length that would work nice for 20m-40m (i.e. in a 30' length) ... sure it would have to be tied down ... but it would work well if ya want to avoid coils

Upon what evidence are you basing your high radiation angle statement?
Modeling shows that short verticals don't have a high radiation angle.

I'm using an Outbacker and it works Great! The CB whip might work OK on 20M and up, but will be lacking on 160M-40M...It's always best to have a resonant antenna, that way more signal is radiated. Using tuners makes the transmitter happy, but doesn't change the antenna's radiation...The transmitter may be putting out 100 Watts, but if 95 Watts are being reflected back into the tuner, the other 5 are going out over the air.

Here in the Midwest I have found aluminum tubing at the scrapyards. It is aluminum conduit and has an I.D. of 2.056 which I found is nice to give a little more clearance for the 2" coil.

Fingerstock from NAPA, that's a new one! I'll have to check that out. Never seen where it's used on autos, where?

If cost is no object, I recommend the Outbacker. Mine (Perth Plus) is mounted on the roof of a Chevy Astro van with their coil spring. The top is about 12 feet in the air. I've hit tree branches with it and it takes it!! I've worked, Sweden, England, Germany, Italy, South Africa, Cuba and Japan with it...usually break pileups and get a reply on 1st or 2nd call.

Another way of saying it is that the "cross section" for scattering (reflection) is
maximum at resonance.

I got out the 1944 article and looked more carefully. Friis does suggest 290K. I missed that previously.

Hi Jim,

Forget the tuner and 108" whip besides damaging your vehicle, unless you mount the tuner on the roof the coax run is too long a run from tuner to antenna, so it won't work well. I use a DK-3 screwdriver on a "L" mount off the tie down eye on my Toyota MR-2, its about 3' off the ground (tops out 10' on 10 meters, 11'14" on 80 meters, with 60" stinger). I run a 25' x 3" copper strip direct from the antenna ground under the whole car connecting everything I could, really lowered the noise level. I get awesome reports with my 706g and 100 watts, If I give 59 I get a +20 in return! 80-10 with the 60" stinger, 40-6 without the stinger (sharper tunign though) and I can still get in the garage. It works better and its A LOT cheaper to do!

Bingo ... thats why i use the ham sticks ... tune em in the phone portion of the band and there ya go ...

The outbacker is far too flimsy and expensive for my blood ... That and having taps is a bad idea ... all ya need to do is get them gunked up with road salt to make them useless

hamsticks are cheap and they work ... ya break it hitting a low branch or because of ice build up you are out 20$ not 200$

Dissipationless Resistance has been debated here ad infinitum! What is it's symbol?

Shall we use R?

Still most in the NG believe that resistance, be it the old fashioned kind or the new fangled dissipationless kind, is "real".

The impedance of a resistance is calculated according to the following formula:

Z=R

Where Z is the impedance and R is the real resistance.

Now I ask, what is "Imaginary Resistance".

i.e. what do we call the device or effect which results in the impedance:

Z=j*R

Where: j is the square root of minus one (j=sqrt(-1))

This is surely not "Reactance". Perhaps this is Dissipationless Resistance.

An imaginary resistance jR is constant with respect to frequency, whereas the two widely known and accepted types of reactance both vary with respect to frequency.

Inductive reactance is a purely imaginary impedance Z which rises linearly with frequency. The impedance Z of an inductance is given by:

Z = j*2*pi*f*L

Where: j is the imaginary unit or the square root of minus one j=sqrt(-1)), pi is the ratio of the circumference to the diameter of a circle, f is frequency in Hertz, and L is inductance in Henrys.

Similarly Capacitive reactance is a purely imaginary impedance Z which varies inversely with frequency. The impedance of a capacitance is given by:

Z=j/2*pi*f*C

Where C is the capacitance in Farads and everything else is the same as above.

But the purely imaginary resistance jR does not vary with frequency! Yet it has a resistance...

Recently it has come to my attention that there might be a formal definition acceptable to the IEEE for dissipationless resistance.

Some of the NG readers may know that I often have CW skeds at 2400Z on 21.005MHz with Dr. Nehoc Nahtan, Ph.D. of the Indonesian Institute of Science in Kuala Lumpur. He operates a homebrew QRPP CW rig only and he is not always in good health, but is one of the most remarkable researchers in the world today. The good Doctor does not have much money at his disposal and so has very little laboratory apparatus to make use of. Hence, most of his results are mathematical.

He is reticent about many of his exploits and results, however he has recently completed a rare proof that Imaginary Resistance is actually Real Resistance since he has recently proved that j = sqrt (-1) is not a valid unit. He shared this proof with me on 15m CW a couple of nights ago...

He sends CW with a hand key and there was some QRM nearby, but after many long years of handling CW traffic on the NTS, my skills were up to the task.

As I was copying this proof line by line, the good Dr. sent BT's between each line, I was amazed... could it be that the imaginary unit j was not actually the square root of minus one! What?

Beginning with the fact that -1 = -1 he ultimately shows by assuming that j*j=-1 or j = sqrt(-1), in a few short lines that -1 = -1, and so by reduction to an absurdity, he proves that j cannot equal sqrt(-1) and that imaginary resistance is probably real!

Here in a few short lines is Dr. Nehoc Nahtan's remarkable proof that j is not a valid unit...

```
.........................................
Given the equality:
-1 = -1
Divide through by one on each side
-1/1 = -1/1
Invert
-1/1 = 1/-1
Take square roots
sqrt(-1/1) = sqrt(1/-1)
Assume that j=sqrt(-1) and substitute
j/1 = 1/j
Simplify
j = 1/j
j*j = 1
And
-1 = 1
Reductio ad absurdium as the Mathematicians say.
.............................................................
```

Thus jR has to be something other than R.

But what?

I suspect, now that we all know that Imaginary Resistance jR is real but different from R, perhaps that is the elusive...

Dissipationless Resistance that the IEEE Dictionary was so ineptly trying to define in it's ill advised article on resistance.

Is dissipationless resistance really jR? What???

Thoughts, comments,

-Peter K1PO

5821. Re: Tire static?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-25 16:47:43 UTC

Message-ID: <Pipv6.39132$s6.2436022@typhoon.kc.rr.com>
Source record: 167644

Yes, steel belted radial tires can create static electricty to the extent of causing some radio interference. If this is what's causing the inteference you should not have any problem in the rain, the water will dissapate the charge. First make sure the radio chassis is grounded to a good ground (no paint) with the shortest piece of wire possible.
Here is my theory of what happens.....A magnetic field can be generated around the tires from the friction of the tires and the road not to mention the spinning "coils" of wire in the steel belted radials that may help increase the strength of this field. This field of electromagnetic induction intermittently jumps to the metal frame of the vehicle and somewhat dissapates. During this time static currents are flowing through the ground system of the car causing electrical interference to radios that require grounding. I may be way off on how or why this happens, but he is how to fix it.
Go to a truck stop or auto parts store and buy a grounding strap. It is a rubber strip with impregnated metal that will bolt to the frame and drag on the ground. It will dissapate any charge from the frame of your vehicle.You have seen these on semi trucks and vehicles of certain racial groups. You could use a small piece of metal chain, but aside from the constant clinking noise it could be a fire hazard from the sparks of the metal being rubbed away. This also may cure a "Shocker", you know, one of them vehicles that you are afraid to close the door on every time you get out because it might shock you. Good Luck, 73's

Message-ID: <3ABE21BA.39506E79@ve2.ele.etsmtl.ca>
Source record: 167645

Actually my main concern is space. The house is about 20'X24' and have neighbours on both sides of the house, same dimensions..... Got also other houses in the back which are pretty much the same size and are also 2 story high (as my house).

I've looked at long wires and G5RV but I dont have the vertical descent for the G5RV ladder segment. The vertical did a fair job for contacts, but I'd like to get something maybe a little better since now it's down due to weather.

A beam standard beam (3 element - 3band) is very much probobly to heavy or has to much wind load for my standard tubular tv tower. It's 40 feet tall.... I also got the tripod on top of the house which is still standing after holding the vertical. I also don't think that the tripod wont be able to hold a standard beam at 3 feet tall....

So for now, I think that a dipole might be my best bet for the limited space for now (other then verticals). Unless you know a type of setup that might permit me to put a beam or other antenna that might serve me best.... I'm open to pretty much any suggestion.

5824. Making shielded ladder-line from coax?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-25 17:27:46 UTC
From: jwg6@cornell.edu
Message-ID: <99l9qi$i43$1@news01.cit.cornell.edu>
Source record: 167648

Is it possible to construct a high-impedance shielded ladder line from coax? I've read that one can use two parallel lengths of 75 ohm coax, shorting the shields together at the ends, to produce a 150 ohm shielded line. However, I'd like the impedance to be more like 450-600 ohms. Any ideas? Could I utilize additional parallel lengths of coax somehow, in combination, to achieve this higher impedance?

I am attempting to feed an end-fed Zepp, but the feeder must run adjacent to a metal building for an appreciable distance, so a shielded line would probably be required.

Thanks!
jg

I'll bet that wasn't on 75m. :-) On 75m, the Outbacker is about 8dB
down from a top hatted bugcatcher.

But you said 15m would be the limit. Why would 20m have a high take
off angle? How did you measure the take off angle on 75m?

> "No we can`t." (kill one constituent of a radio wave without killing the
> other)
>
> I am aware that Maxwell says:
> 1) When an electric field changes, it creates an magnetic field.
> and:
> 2) When a magnetic field changes, it creates an electric field.

Maxwell's equations are a particular formation of the experimental laws of electricity and magnetics developed by Gauss, Faraday and Ampere.

The equation:

curl B = u * e * dE / dt + u * J

Where:
B = magnetic flux density vector (Wb / m^2)
E = electric field vector (V / m)
u = permeability of media (H / m) = 4 * pi * 10-7 in free space
e = permitivity of media (F / m) = 8.85 * 10^-12 in free space
J = conduction current density (A / m^2)

Is a statement that the rotational component of the magnetic field at any point is equal to the weighted sum of the conduction current plus the time rate of change of electric field.

It does not state one causes the other, only that a particular simultaneous relationship exists.

Another other relevant equation is:

curl E = - dB / dt

Which states that a rotating electric field exists equal to minus the time rate of change of magnetic flux at any point in space.

Hypothetically, a time varying electric field could exist without a magnetic field if the electric field was rotation free, and just the right conduction current density was present. Such conditions are possible in semiconducting wires but are irrelevant to the topic of antennas and Faraday shields.

> Perhaps I should have said: You can short the electric field without
> killing the magnetic field.

While the first equation allows for the existence of circulating
magnetic flux without a corresponding electric field (current flowing
through a wire), the second equation
states that whenever a time varying magnetic flux is present, so is a
circulating electric field. You cannot have a time varying magnetic
flux without a corresponding time varying electric field.

> My recollection is that a short on a transmission line forces the
> electric field to zero at the short, and it also forces a reversal of
> electric field polarity as it is changing the direction of travel. Also,
> the forward and reflected voltages must add to zero.

The voltage between the two conductors is zero at the short but the
electric field in the dielectric still exists, primarily due to the time
varying current flowing through the short.

The usual way to solve such a problem is to postulate the existence of a
forward and reverse wave, each which is a solution to Maxwell's
equations for the continuous transmission line. The amplitude and
phasing of the individual waves are chosen to satisfy the imposed
boundary conditions. e.g. The voltage must be zero across a short
circuit and the current must be zero at an open. If a combination of
waves can be found such that when superimposed satisfy all of the
constraints, then the superimposed set is guaranteed to describe the
voltage, current and fields everywhere in the system.

> My recollection is that energy is conserved when either the electric

> forced to zero (at an open circuit) by a very temporary transfer of all
> the energy, it amounts to a double, to the surviving field. The
> subsequent energy redistribution to a 50-50 split is very rapid.

Energy is always conserved. Some may leave the system by radiation or
conversion to heat but energy never unaccountably vanishes. The total
energy in a transmission line system at any point in time is the sum of
the energy stored in magnetic and electric fields. When standing waves
exist there is no requirement for a 50-50 split. Consider the case of a
open circuited transmission line much less than a quarter wavelength.
The input impedance is capacitive and the majority of the energy stored
is in the electric field.

Peter, non-dissipative resistance is 'real', even though no energy is converted to heat during current flow. Being 'real' it is in no way 'imaginary' that would entail the use of 'j'.

I know I'm being redundant by reminding that R = E/I, which is simply a ratio, and R is a resisTANCE, not a resisTOR.

I agree that the IEEE erred in calling both dissipative and non-dissipative resistance 'resistance'.

However, because the input impedance, or 'surge' impedance' if you will, of a lossless transmission line is determined by the sqr root of L/C, and is also determined by the simple ratio E/I, there can be no conversion of electrical energy to heat at that point. Therefore there is no dissipation in the resistance appearing at the input of the line, as long as dissipation is defined as energy converted only to heat. What happens downstream, for example at the terminating load, is irrelevant to the situation at the line input.

I find it hard to understance why some people have difficulty in appreciating the difference between dissipative and non-dissipative resistance. Seems clear as a bell to me.

herr doktor,

Curious hmmm? Surprised to be found in the list? I'm sure the
speaker selection committee is unaware of your posts in this forum.
After-all, this is just a hobby activity and your gaffes, spectacular
as they may be, are not of interest to the general (or even specific)
scientific community. (I even cleaned up your spelling above so not
to embarrass you with your peers.)

BUT, as you have noticed and anticipated, yes, there is a convergence
of topic and a collision of speakers. You have remembered to take
your aspirin haven't you? Remember to take the bottle with you.
:-(

Is it possible that this event will also mark the announcement of the
winner of the FRACTAL CHALLENGE held last winter? You could present
Steve Best his $1000 award during this activity. You may notice that
his talk includes several of those designs that bested yours quite
handily.
;-)

A little time with a communication monitor and a 81dB attenuator.

20m,40m were through personal experience. We know that if one would enjoy communicating (locally) a lower take off angle would be better, however, on those bands since my base station here would end up being lower than the lobe and hence a far lower signal

The spacing from conductive surfaces required for the popular window
line is only about 2ï¿½". That should be a problem and you'll have lower
losses that trying the twin coax route.

Hi jg,

Yes. You could try 9 50 Ohm cables. The cables run parallel, but
electrically they are connected in series at both ends. However, it
probably is not a good idea to have both ends wired to 450 Ohms (just
one end naturally), I imagine you would like to see a 50 Ohm input.
With 9 50 Ohm cables, the input end would be wired in 3 parallel
groups of 150 Ohm series connections. This would only work if all
lines are quarterwave (or beaded up). It is also absurd in the
extreme because the same architecture can be performed with a Balun
and more suitable transmission line materials. Run one 50/75 Ohm
cable past the building and feed the load through a Balun.

Peter, K1PO wrote:
"Here in a few short lines is Dr. Nehoc Nahtan`s remarkable proof that j is not a valid unit."

It doesn`t look like Chip`s work to me. If Chip were to invert one side of an equation, he would invert both sides..

Mathematicians would use the operator "i" and not "j". They are identical, but we use j to show the operator means the attached magnitude is phase shifted from the real (or resistance) axis by 90 degrees.

Dissipationless resistance is not associated with the j operator as like any other resistance its location is always on the real axis (usually the abscissa).

John:

Dr. Nehoc cannot afford the expense of the IEEE Dictionary and so he was forced to work from first principles in an effort to figure out what dissipationless resistance was.

He assumed that there must be a dissipationless resistance, since the IEEE says so, and since clearly not many agree on what it is... he assumed that the only thing it could be was an imaginary resistance, and so he set out to see if he could prove that imaginary resistance jR is really a real resistance.

Now that he has proved that j cannot really be sqrt(-1), can you find the flaw in his proof? He now believes that we can now put dissipationless resistance on a sound mathematical and technical footing. But he needs some help with his laboratory experimentation. I have been working from plans he is slowly sending me each night on 15 m CW to build one of these imaginary resistors.

BTW... all of the usual circuit analysis works for this imaginary resistance, no problem... for instance....

Ohms law holds even for imaginary resistance, and so...

V = I*j*R is valid.

The power being "dissipated" in that imaginary resistor is then purely imaginary (and of course dissipationless):

P = V*I = I*I*j*R = j I*I R

However there is no energy being stored!!! As there would be in an inductor or capaitor.

No energy being stored, current is flowing, and the power is imaginary.

This must truly be dissipationless resistance, no?

What happens if you put a "real" resistor of value R in series with an "imaginary" resistor of value jR.

Then you get a total resistance of R+jR = R(1+j). The impedance of this combination is:

Z = R(1+j) and the magnitude of the impedance is sqrt(2)R. The phase angle is clearly 45 degrees.

And no energy is being stored!

What is the Q of this strange beast?

If the imaginary resistance was an inductor in series with the real resistor then the impedance clearly would be storing energy, and the Q would be:

Q = (2*pi*f*L)/R

What is the Q of an imaginary resistor in series with a real resistor?

Does it have a Q?

Is it a dissipationless resistor or is it a real resistor?

What????

When I finish building the imaginary resistor from Dr. Nehoc's plans I will share the experimental results with the group. Last night he sent me another installment of the plans... it's agonizingly slow copying those plans on 15 CW from his hand sent keying. Sort of like an extended SKN, heh, heh.

This week I have to go out and get some of the materials that he requested to go into the "mix" for the imaginary resistor. So far his plans read like the old carbon composition resistor recipe with the exception that the carbon powder is unusual. Do you know of a good supplier of diamond dust? He also wants me to get in a good supply of birefringeing optical grade glass, and some titanium dust. He says I will need a very high temperature crucible in which to "cook" the mixture for the imaginary resistor.

I can't wait to get the rest of the recipe... Any night just tune around 21.005 MHz and listen for a weak CW signal near midnight to hear him sending me the plans.

Soon we'll know if the imaginary resistor is really the dissipationless resistance that the IEEE Dictionary speaks of.

BTW.... Dr. Nehoc asked me to request any mathematicians on the NG to examine his proof that j is not sqrt(-1), and to share with us any concerns that they might have with his proof.

The good Dr. is a genious and I have no doubts, but he always tends to underestimate himself. I think that he is worried that I might spend too much of my hard earned money on diamond dust before the proof has withstood the test of time.

Food for thought...

Best Regards,

-Peter K1PO (The imaginary resistor salesman!)

The Luneburg lens makes a small vessel look the size of an aircraft carrier on the PPI display. 28 years ago they had RADARs that were hardly affected by rain.

> As my ship was 600 feet long displacing 25,000 tons, we had a long

I spent 6 months in the NOrth Sea on 100 Ton German built Air Sea Rescue boats whose prime purpose at times was to clear the fishing boats out of the bombing practice range. At other times the primary function was to measure depth along the sandy nudist beaches of Sylt. You can guess what was my favourite activity. We had DECCA Radar and SAHRA which consistewd of two YAGIs mounted on the mast head slightly diveregent straight ahead and an ADCOCK on the fore deck. A downed pilot that had inflated his Mea West would automaticaly deploy his beacon antenna. by steering the boat/ship so that the signal showed on the cilcular Lisajouex display at the top you would be heading for the Victim. At close range it was neccassary to switch over to the Adcock for a bearing.

>They weren't entire low tech, as several switched on
> their own radars when we appeared, my radar began to fill with fine

When they go bang the lucky ones don't hear them. I live in the middle of a
triangle whose corners are marked by a factory that turns them out a store
that waits the day when they will be required and the Labs wher so much of
of the fundamentals are explored. Would you say that we are a prime target?

Both sides had Window.
I can remember playing with the stuff when I was a kid after Gerry Raids. There was even a rumour that it was poisoned to kill the kids that put it into their mouths; this was about the time that Butterfly bombs were being used, Any poison was probably the arsnic or some such that it was common to put into paper in store to prevent the rats from eating too much of it. The paper tapes used for TTY are /were often imprgneted with poisons for the same reason, so if you have any old stock be careful lest you get ill from hamdling the stuff.
The stuff that I remeber was coted with a thin black coating so that it did not reflect in the search lights and give the game away, under tyhe thin black coating was a conductive coating onto a paper base. I seem to remeber a yellow stripe, upon reflection,(sic) this may have been a colour coding, I do not know if it came in a variety of types for various purposes.

>The lengths of the strips were carefully chosen to be resonant. If the
> strip is not resonant the wave passes right on through the strip.

As the Brits were using RADAR in the shortwave region as well as the adapted NT 277 10 Cm type strips that would fool both RADAR would have been difficult if reliant solely upon resonance. The cloud of window/chaff has to have reflection characteristics similar to a squadron of Bombers, pure resonance might give the game away, the chaff is only effective as a deception for a short period so it must be deployed tactically.

Homebrewing a SuperTurnstile (or BATWING as it is commonly called
in the broadcast circles) is not that hard....the Batwing is merely
a slot antenna made out of wings...I have the docs on how to build
one at work...will post them here asap...
At 23cm you should be able to make the wings out of stamped aluminum
with 90degree tabs at the top and bottom for mounting to a mast/pole
of proper size and strength.
Also another good antenna for horiz omni work is the traveling helix
antenna...actually two vertical helix antennas...the top in opposite
sense from the bottom one...fed in the center with coax and the far
ends grounded (allows for low voltage HI current feed to act as a
deicer!)..the vertical component in each helix cancels because of
180deg phase difference...I will also post that as well..
The antennas are in the ANTENNA series of books by Lee.

Yeah...get a 2mtr Larsen 5/8wave NMO mount type...don't cut
the whip! It should work fine on BOTH bands...use a diplexer
from Comet or Diamond (or build your own!) for dual band operation.
For horizontal use, you probably need to try a Squalo design or
Halo design...

Why go to the trouble of 3 reflectors ? Unless you need some very high
F/B ratio and I doubt that you will get that with a 5 element beam even
with the 3 reflectors. They will do nothing for the gain.

I am pleased that you feel that you can speak for the Ham fraternity, but if the rest are as unruley as the lot in this news group I doubt that anyone could claim to speak for Hams as a general class. :)

> >>I am in very direct contact with
> >> that segment of the ham fraternity that needs to think about noise
> >> temperature: everybody accepts the definition that 290K is a reference

Ian we all need to think about noise temperature if we want a good station. I doubt that those with their head screwed on properly want to waste their money and time on a substandard station. The competative spirit is obvious from the up take of Contests.

> >Valid when Noise figure is measured by sophisticated laboratory

Understood, but not everybody uses a noise diode or noise tube to calibrate their equipement. The price of such commercial instruments precludes their use by most Hamns I would think. However the construction of Hot and cold

loads can be a kitchen table exercise which many Hams could adequately
accomplish.

> That then leaves the user to apply a further correction for the actual
> temperature of the noise source, once again to reference everything back
> to 290K. It's awful hard to get away from.

Only if you want to communicate your system performance to a third party for
that third party to use the values obtained for some further calculation.
Otherwise the system passes into one of two categories GOOD or BAD.

> BTW, the latest noise heads have a built-in temperature sensor right at
> the output attenuator (which defines Tcold) and the noise figure
> analyser reads and applies this automagically. With older noise sources,
> there is a small error because you can only measure the temperature

> fraction of a watt, and thus has internal temperature gradients.

Nice to see the care which instrument manufacturers are taking. I'm quite
sure that the instrument companies for whom I designed instruments exercised
equal care withing the available technology and state of the art at the
time. The company owners may well have been primarily interested in profits
however the guys in the Lab took a peresonal pride in the quality of the
instruments that they were charged with inventing.

> >Presumably you are familiar with the Dicke Radiometer?
>
> Yes, although NPL now uses other techniques below 26.5GHz.

With low level signals it is a bit wasteful I must admit. :)
However it is again something which the average Ham could make and calibrate
and use.

5850. Re: Station/tuner ground

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-25 21:14:46 UTC
From: Greg <greglh@gte.net>
Message-ID: <3ABE5FF0.C2BA705C@gte.net>
Source record: 167521
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.misc

Jason;
My situation required 're-learning' about grounds as I operate my shack from the second story of my house.

My ground rod does indeed serve as my protection against lightning strikes and defective equipment shorts, etc.
However, the connection was far too long (about 16 feet) to keep my shack equipment at zero RF potential. (My antenna is a vertical, thus even more importance attached to having a good RF ground at the shack)
Many reports of RF in the audio, poor results with otherwise reputable antenna tuners, etc. caused me to install a seperate RF ground system.

I used the MFJ Artificial ground unit to optimize a counterpoise antenna consisting of multiple wires (bundled) but each cut to approx. 1/4 wavelengths for 80 thru 10 meters, fed from the MFJ. The results were immediate, though not in the way I expected. My performance at 80 and 40 meters was vastly improved, with the MFJ showing a pronounced increase in RF current into my counterpoise radial(s). I expected my Ground stake to provide a reasonable ground for these bands, but not so.
What I expected was to see substantial ground current flowing into the coutnerpoise at higher bands (with the theory that my lead from the ground stake was too close to a 1/4 wavelength for these bands) Yet, 20 thru 10 meters seem less dependant on the RF ground system.

Anyway, the RF problems are gone and the system improvement with an effective RF ground is pronounced.

So much for the concept that 'one ground fits all'. You need at least 2 types. (common mode ground systems are another, even more difficult to install system, but highly regarded for RFI reduction)

Now you know what I know.

Bart, WB6HQK wrote:
"The total energy in a transmission line system at any point in time is the sum of the energy stored in magnetic and electric fields. When standing waves exist there is no requirement for a 50-50 split,"

The standing wave patterns with 90-degree offset between voltage and current confirm that. If we had a lossless line with an open or a short we could have points of disappearing voltage and other points of disappearing current, distributed periodically along the line. Minimum-current points are displaced from current maxima by 90-degrees. The transmission voltage has the same type of pattern but is displaced by 90 degrees from the current so that current maxima correspond to voltage minima and voltage maxima correspond to current minima. The line is resistive at these maxima and minima points of the SWR pattern.

One view of the relation between volts, amps, and their associated fields is that volts and amps are the producers and the fields are the products. An argument for the reverse situation can also be made.

It seems reasonable to me that in a short on a transmission line where the current doubles you get a corresponding increase in the magnetic field produced by that current and that the magnetic field change would give a corresponding change in the electric field. These E&H fields make up the reflected wave.

In a transmission line with standing waves, the energy may not be evenly divided between the E&H fields as it is in free space where the impedance is a constant 377 ohms, but the energy flowing in each direction on the line is constant. My Bird wattmeter has no problems with SWR.

Best regards, Richard Harrison, KB5WZI

Excellent. Thanks, gentlemen, for the responses! I'll go with the ladder line and standoffs.

I am not after a 50-ohm load; rather, I'm planning to run the zepp on 5 bands, through a balanced coupler. It is a compromise, to be sure, but in this location it's gonna to be the best I can do.

Thanks again and 73 all...

"I need the vertical spacings of the 3 reflectors (2m yagi)."

The RSGB VHF-UHF Manual has a 2-m yagi using a "trigonal" (3 stacked elements in a plane perpendicular to the plane of the other elements) reflector.

The reflector rods are 40 inches (101.6 cm) long.

Spacing rod-to-rod between the 3 reflector rods is 1/4-wavelength or 52 cm at 145 MHz. The middle rod in this reflector is spaced 40 cm from the radiator.

This information is found on pages 7.10 and 7.11 of the 3rd edition.

Best regards, Richard Harrison, KB5WZI

No it isn't. The lossless line has either no resistance or infinite resistance every 90 degrees from the short or open. It also is impossible to feed power into the line. The line is either an infinite impedance, a perfect short, or a pure reactance.

None of this has anything to do with Farday shields.

>It seems reasonable to me that in a short on a transmission line where
>the current doubles you get a corresponding increase in the magnetic
>field produced by that current and that the magnetic field change would

>up the reflected wave.

What good does discussing a riddle do? Why do you say the current doubles at a short? It would depend on the rest of the system. If the line was lossless, it would be impossible to feed power into the system (unless you had infinite voltage 90 dgrees away). The input impedance of a lossless 1/4 wl long shorted line would be infinite.

Even Roy's big QRO rigs won't cause current to appear at the short.

>In a transmission line with standing waves, the energy may not be evenly

Even if you were after 50 ohms, you would not get it with the parallel
coax at one end and series coax at the other....or a transformer or
impedance transforming balun.

That's because the antenna (the load end) is not 450 ohms.

That is not a "perfect example" unless the end result of removing the code
requirement is that you can no longer use CW. If, after removal of the code
requirement, you or anyone else that wishes to learn and use CW is free to
do so there is NO parallel.

> I understand how a nuclear reactor works, but I would never be allowed to

Again, unless the end result is that it becomes illegal to use CW the
comparison is invalid.

That's funny. A whole branch of physics is devoted to heat, because
of its critical importance, and a very precise definition of it is used
implicitly in all energy systems, including emphatically electrical
engineering. Perhaps if the IEEE *had* tried to define heat precisely,
they'd have discovered the folly of their "dissipationless" resistance
definition.

I have been using the MQ-2 for about a year and I am very happy with it. Unlike the other poster who had one of the older versions (made by a different company I believe) mine has very good SWR curves - as advertised - a little narrow on 20 but manageable. The antenna has good directional characteristics, I have never lost a spoke, and I have run a full KW into it without harm. Check out the reviews on www.eHam.net to see what others have to say. If you want a small directional antenna I don't think you can go wrong with this one.

Shielded twin line is an utter waste of time and money for antenna feeders. Shielding serves no useful purpose. And it's far more lossy than necessary.

If you want a really negligible loss twin feedline for a multiband HF dipole make yourself an openwire line from 10 or 12 AWG enamelled copper wire spaced 3, 4 or 6 inches apart. Beautiful stuff !

So is the conversion of energy to *any* frequency of EM radiation. Radiative transfer is not limited to the IR portion of the spectrum. It occurs at any frequency. (What do you think is the transfer mechanism of the "thermal noise" received at HF, or even ELF?) All radiation is heat in the formal sense that it is an irreversible radiative transfer of energy from a body.

That's what thermodynamics says, and thermo *is* the authoritive field of study of heat.

Sure it is. The outcome of the argument is not the issue. The issue is that
you have a group of people with absolutely no expertise on the subject
forming an opinion based on personal feelings and self interest, that they
are trying to convince others is correct.

Different disciplines have different definitions. Webster's definition
of heat is apparently sufficient for the IEEE. How do you explain why
the characteristic impedance (50 ohms) of a coax transmission line
doesn't dissipate energy, i.e. convert it to heat? Why does RG-174
dissipate so much more energy than 9913 when their Z0's are identical
at 50 ohms? (FYI, "ohms" is the unit of electrical RESISTANCE).

In the center of the vehicle. Cable doesn't matter for radiation pattern.
Mount doesn't matter for radiation pattern. Pickup. Chassis. Nope. I
seriously doubt that you used a helicopter for your tests. That's
the only accurate way to determine take off angle. Short verticals
have approximately the same takeoff angles as 1/4WL verticals.

I recall an OT telling me the very expensive cars in the 30's
had suppression of some sort possibly just a strap. on the brake
drums to improve radio reception. Conceivably disks could do the
same thing as they spin around as usually they 'just' touch
the pads and it might generate a staic charge.

Just a thought

Cheers

Not familiar with hamsticks, but are they single band? If so, $20 X 10
bands (my Outbacker covers 10 bands) is $200, so I wouldn't consider the
Outbacker too expensive at $289. I challenge you to break an
Outbacker...fiberglas rod covered with (I believe) and Epoxy paint.
Mine will rip the spring right out of the roof before it will break the
antenna.

An old-timer told me how they used to get rid of tire noise. He said they introduced powdered graphite into the tires and re-inflated them seems the graphite coated the insides and create enough capacitance to dissipate the noise.

they are 20 cdn a peiece ... what i was saying is the initial investment is the same ... but replacement cost is far cheaper. Try having a coat of 1/2" solid ice on one and smack it into a tree down a road at 80km ... itll snap like a twig. Up here ice builds up on em real well and thats a big consideration.

If i bust one i pay my 20 and get a new one ... not 290usd!

"W6DKN" <w6dkn@qsl.net> wrote in message news:yivv6.3230

> Sure it is. The outcome of the argument is not the issue. The issue is that you have a group of people with absolutely no expertise on the subject forming an opinion based on personal feelings and self interest, that they are trying to convince others is correct.

The people who oppose the Morse code exam statute 47 CFR 97.503(a) are not required by law to be proficient in manual Morse code reception in order to petition their government to delete the rule. The Amateur Radio community have ignore the facts and laws for too long. Your delusion that only Morse code experts can decide this matter is pure non-sense.

In its 1999 License Restructuring Decision , the FCC acknowledge the effect technological changes on the need for Morse code proficiency:
"the design of modern communications systems, including personal communication services, satellite, fiber optic, and high definition television systems, are based on digital communication technologies. We also note that no communication system has been designed in many years that depends on hand-keyed telegraphy or the ability to receive messages in Morse code by ear. In contrast, modern communication systems are designed to be automated systems."

In a October 27, 1997 briefing paper prepared for digital television broadcasters, Mr. Erwin G. Krasnow noted the effects of technology on regulation: "The Supreme Court has observed in CBS v. DNC that the FCC must "walk a 'tightrope' to preserve the First Amendment values written into the Radio Act and its successor, the Communications Act." After referring to its Red Lion decision, the Court noted that "[t]he problems of regulation are rendered more difficult because the broadcast industry is dynamic in terms of technological change; solutions adequate a decade ago are not necessarily so now, and those acceptable today may well be outmoded 10 years hence." Columbia Broadcasting Systems, Inc. v. Democratic National Committee, 412 U.S. 94, 117 (1973)."

Because of technological and operational changes, the manual Morse code exam is unnecessary. Its use as a licensure examination element to authorize frequency bands and emission types, other than manual Morse code operation, is arbitrary and capricious. The exam is even arbitrary to authorization Morse code operation, since such operations can be conducted by computer control.

The ITU rule S25.5 forces the FCC to impose a requirement upon its citizens that is unlawful. 5 U.S.C. 706, "Scope of review" provides:

To the extent necessary to decision and when presented, the reviewing court shall decide all relevant questions of law, interpret constitutional and statutory provisions, and determine the meaning or applicability of the terms of an agency action. The reviewing court shall - (1) compel agency action unlawfully withheld or unreasonably delayed; and (2) hold unlawful and set aside agency action, findings, and conclusions found to be - (A) arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with law; (B) contrary to constitutional right, power, privilege, or immunity; (C) in excess of statutory jurisdiction, authority, or limitations, or short of statutory right;
(D) without observance of procedure required by law; (E) unsupported by substantial evidence in a case subject to sections 556 and 557 of this title or otherwise reviewed on the record of an agency hearing provided by statute; or (F) unwarranted by the facts to the extent that the facts are subject to trial de novo by the reviewing court. In making the foregoing determinations, the court shall review the whole record or those parts of it cited by a party, and due account shall be taken of the rule of prejudicial error.

The FCC has dealt with the Morse exam matter more directly. The telegraphic examination was removed as a requirement to qualify for Technician Class operator license in 1990. In its Report and Order (FCC Record 7631), the FCC stated:

(a) "For the amateur service to achieve its purpose it must have the participation of as many qualified persons as possible who desire to pursue that purpose. Modern commercial and military electronic systems require engineers to design them, technicians to install and maintain them, and a technologically literate citizenry that can use them. The amateur service should, as it has in the past, attract technically inclined persons, particularly the youth of our country, and encourage them to learn and to prepare themselves where the United States needs expertise. We do not foresee that telegraphers will be in as great demand by future systems as will electronics and communications experts."

(b) "Telegraphy skill has been required for each person who has ever been issued an amateur operator license in the United States, including the current 493,000 licensees. Mastering the Morse Code was an arduous task for many of these licensees, and by developing their telegraphy skills they expressed their intense desire to become amateur operators. It is understandable, therefore, that there are licensees who are reluctant to share the amateur service frequencies with new licensees who have not made a similar effort to master the Morse code. We conclude, however, that telegraphy skill is not so essential to proper operation of a station that transmits exclusively above 30 MHz such as to justify turning away otherwise qualified persons who do not possess the skill. The Notice, furthermore, did not propose to delete the telegraphy skill requirement for a licensee to be the control operator of a station transmitting below 30 MHz where telegraphy communications take place extensively and worldwide communications are possible. The sharing of frequencies between codeless class licensees and other licensees can take place on frequency bands above 30 MHz where telegraphy operation is minimal and where the transmission of

the more modern emission types such as data, image, phone, pulse, RTTY, and spread spectrum, predominate."

(c) "We do not concur with the comments alleging that the passing of a telegraphy examination is an indication of the examinee's good character, high intelligence, cooperative demeanor, or willingness to comply with our rules. These traits are also found in individuals who have not passed a telegraphy examination rather than being exclusive to those who have passed such a test. For regulatory purposes, passing a telegraphy examination is no more and no less than proof of the examinee's ability to send and receive texts in Morse code at some specified rate. With respect to comments that make claims for the superiority of telegraphy over other types of communications, we do not consider these arguments as germane to this proceeding. The Notice did not propose to discontinue the authorization of telegraphy CW emission types on any amateur service frequency. The amateur service in the future, as it has in the past, can provide to those who personally desire to do so the opportunity to communicate by telegraphy."

The 13 and 20 word per minute telegraphy examination was removed as a requirement in 1999. The FCC stated in its Report and Order (FCC 99-142) for WT Docket #98-143 that:

(a) "the public interest will best be served by reducing the telegraphy examination requirement to the minimum requirement that we have found that meets the Radio Regulations" ;

(b) "an individual's ability to demonstrate increased Morse code proficiency is not necessarily indicative of that individual's ability to contribute to the advancement of the radio art" ;

(c) "such a license qualification rule [Morse code exam] is not in furtherance of the purpose of the amateur service and we do not believe that it continues to serve a regulatory purpose" ;

(d) "the amateur service is fundamentally a technical service, the emphasis on Morse code proficiency as a licensing requirement does not comport with the basis and purpose of the service" ;

(e) "reducing the emphasis on telegraphy proficiency as a licensing requirement will allow the amateur service to, as it has in the past, attract technically inclined persons, particularly the youth of our country, and encourage them to learn and to prepare themselves in the areas where the United States needs expertise" ; and

(f) "telegraphy proficiency is not a significant factor in determining an individual's ability to provide or be prepared to provide emergency communications" .

The Morse code requirement is finished. Give it up before you destroy the entire Amateur Radio Service.

Larry, KC8EPO

Matching, or lack thereof, will change the magnitude of the radiated
RF but it will not change the radiation pattern or take-off-angle.

Windoms are supposed to have a feedpoint impedance close to 300 ohms
so it's probably a 6:1 or 4:1.

Project the dozen who post here into the general ham population and
you get tens of thousands.

Kind of a silly example, wouldn't you say? A vast majority has never fired a thermonuclear device either, and yet they would have you believe that based on their feelings and opinions, you should have to give up your personal thermonuclear device, if you had one.

Or taken even further, take the anti-drug crowd - the vast majority of them have never even shot heroin, and yet they would have you believe that based on their feelings and opinions, you should have to give up your needle.

Because it is the only national ham radio association in the US, and as such is the sole protector of every US ham's interests, rights and privileges. Because without it, ham radio would cease to exist after losing every Hz of spectrum to special interest groups who, unlike you and your CB buddy, are well organized and represented.

> Who cares?

Whoever cares about the future of ham radio, not only in the US, but in the entire world.

> The ARRL is losing members day in and day out. They have to ask themselves,
> "Why?"

Provide data to support this claim, please.

> The real reason for this loss of members is simple.
> 1. It costs too much and you get nothing back.

Bullshit. See above. What's the cost nowadays, $34? You mean to tell me that you "can't afford" lousy $34 to be a part of the organization that protects *your* interests? You probably blow more than that daily on beer.

> 2. The magazine is too full of voting and political agendas.

Bullshit. Nobody forces you to read those pages, nor the rest of the magazine for that matter.

> 3. Nobody really cares about the ARRL.

Bullshit. Nobody meaning you.

Of course the outcome is the issue. If it weren't then there would be no
debate either way. Besides, what "expertise" is needed to see that
mandatory testing for only one mode out of dozens is wrong? Those that have
"expertise" on the subject are also basing their opinions on personal
feelings and self interests and trying to convince others they are correct.
And it isn't only those that have yet to pass the code requirement that are
```

against it. If it was about to be made a criminal offense to learn or use the mode you would have an argument. As it stands, I can only see the code test being valid if EVERY mode that might possibly be used is tested for proficiency. Then and only then would the code test have a valid leg to stand on.

Hi Jason,

Ground loss is an empiric science. Theory cannot accommodate the vast
number of variables and the local geology is rarely known to the
degree required to reduce this to a formula. There are survey maps
that reveal these issues, but often they are restricted to commercial
frequencies and rarely outside of the AM band. However, they are
useful as indicators of soil conductivity and this information is
generally extrapolateable or useful as a basis of comparison.

As for conventional wisdom....
Your link seemed to have its share. The coverage was even handed and
mindful of the realities.

5890. Re: Faraday shield antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-26 07:01:35 UTC
From: Cortland Richmond <ka5s@earthlink.net>
Message-ID: <3ABEE85F.85A65520@earthlink.net>
Source record: 167561

I did the experiment. I am now listening to a local AM radio station on a loopstick-equipped radio
inside an aluminum cylinder about 7 inches in diameter and 30 inches long.

A radio using a short whip, placed in the same tube, is unable to receive the same station, even
though reception is more than adequate when it is outside the cylinder.

This is not really analogous to the situation we've been discussing, of course, since the loop
structure is in this case differently oriented with respect to the shield. Coming as close as
possible, by orienting the loopstick so the turns, not the core, are aligned with the long axis of
the tube, signals are received.

There is no reception when the core is oriented with the long axis of the aluminum cylinder, as the
tube is then an efficient short circuit of the magnetic field. However, that configuration is not
used in the normal shielded loop, since the loop turns would have to be wound concentric with the
shield's minor circumference to duplicate it.

This experiment does demonstrate that the magnetic field component of an electromagnetic wave can
pass when a receiving loop antenna is enclosed completely inside a conducting cylinder, and strongly
suggests that the electric field cannot.

If you should wish to try it yourself, the shield I am using is a Home Depot extendible aluminum
duct, "deflecto" model A078-5. I used an AOR AR8000 with the whip removed. THis radio has a loopstick
for AMBC reception. The radio used with an electric-field probe antenna was an Alinco DJ-X10, which
has no loopstick. This is not small enough to stand up when the tube is horizontal, but I used an
antenna that could be bent 90 degrees.

If you try this, you will see some attenuation due to shorted turn effects, which can be expected
when the loopstick is enclosed in metal at the ends, as this is. However, a shielded loop has a gap
which makes that moot.

Well, he's right when he says a magnetic loop will receive the same without a shield as with one. If it's well balanced, it won't even need a shield to get good nulls. And THAT has been well discussed here.

FWIW, the ARN-59 ADF (about which HOPE I have forgot most of what I knew) loop was unshielded, wound on a rotating ferrite core, and got good balance anyway.

About the rest, I took Tom up on his suggestion and did the experiment he proposed. I have posted the result here in another message.

Let's not forget that in the near field the ratio between electric and magnetic components of the field is much different than it is at a distance.

I suspect some of our differences may be accounted for by the presence of near field conditions around a conducting object which intercepts a wave.

Message-ID: <3ABEEE3B.E26BC8C9@earthlink.net>
Source record: 167567

This is where Tom and I disagree; I say there is no "spilling over" inside the shield. I believe I can and have demonstratedthist by failing to detect an electric field inside a tubular shield with a device sensitive to one; he says I have not.

We may confuse ourselves, however, if we say that the electric-field short (my opinion) of a shielded loop is some universal cure for noise. If the antenna is located near a noise source whose near field is predominantly electric, then it can indeed reduce that noise. But by the time you get some distance away from a radiator, the electric and magnetic components of the field have reached a ratio of 377 to 1 for both noise AND desired signals.

Roy Lewallen wrote:

> Are you saying that very little E field exists inside a coaxial cable?

I realize I did not answer your question. No, that is NOT what I am saying. What I am saying is that the external electric field is not seen inside a shield, because the shield is a sufficiently low impedance that it short circuits the E-field before it can be seen by an inner conductor.

This is the same as saying that the internal E-field of a coax is not seen OUTSIDE a coax because the shield is a good conductor, no?

I don't speak for them, but the amateurs around the world who are
actively engaged in measuring noise temperature are a close-knit group.
We know who else is involved, we correspond by e-mail and we get
together in person whenever we can. Some of us measure noise figure
professionally while others are pure amateurs, but we all do our utmost
to work to professional standards.

There is a lot of published information on the web, in amateur
conference proceedings, in specialist amateur VHF/UHF/microwave
magazines, and even in a book or two, of which you don't seem to be
aware.

The reality is that for a few pounds or dollars, you can make a highly effective noise diode source that will work from HF through to the low microwave bands. And you can have it calibrated against commercial sources at a "Microwave Round Table" Sunday for free.

The only difference between an amateur and a professional diode noise source is likely to be that the professional source has a flatter calibration curve, and goes to higher frequencies.

AFAIK, tube noise sources are obsolete. Their theoretical self-calibrating feature doesn't meet modern requirements for accuracy. Perhaps even more importantly, they don't meet the more recently understood requirement for a minimal impedance change between the ON and OFF states. Solid-state noise sources (even the base-emitter junction of an ordinary RF transistor) generate very high levels of noise, which allows impedance-stabilizing attenuators to be inserted between the diode and the output. Tube-type noise diodes don't generate enough noise to allow this. I threw one away last year because it was of no practical use any more.

>However the construction of Hot and cold
>loads can be a kitchen table exercise which many Hams could adequately
>accomplish.

Not unless your kitchen has hot and cold running liquid nitrogen :) Seriously, it is by no means as easy as you suggest, not if you're going to do a really accurate job. If you choose to use conveniently accessible temperatures, the temperature baseline is short and you run into trouble with making accurate dB measurements. On the other hand, if you do have access to solid CO2 or liquid nitrogen, you run into problems with changing impedance of loads, and corrections for noise contributions from the parts of the system that are not at the same temperature as the reference load. In other words, it is not a simple job in practice.

Your theoretical speculations are accurate as far as they go - but as ever, they don't go far enough to account for the realities that are well known to people who are actively involved.

The only thing is that autotuner is not really what I'd consider a very good "base" loading coil. I don't really consider that base loading because the coil is not on the radiator itself. "Or don't think it is anyway". I may be wrong there... You can do real well with true base loading , but you need a good ground system under it. The current distribution is better on the center load, but more turns needed, and more coil loss. I think the lower the freq , the more an advantage to a center loading coil. On say ten meters with the antenna right in the middle of the roof on good metal, I don't think you would see much difference between the two. But I'm assuming a good high Q base loading coil, the same as used on the center load. On 80m, you can see quite a difference between the two types usually. MK

==========
I have the 18th Edition. On the same pages it says nothing about calculating ground losses at HF. It just describes a simple method of measuring soil conductivity at 60 Hz which is a different thing altogether.

In any case soil permittivity is as important as conductivity at HF.

Hi Courtland,

Read Roy's post about the field ratio.

It will explain a lot of things to you, if you read it carefully.

All of my antennas and amplifiers are 100% efficient, so are my light
bulbs. What about your's Reg?

The energy out is equal to the energy in.

Nonsense Rob.

It does not change the TOA, it simply changes the enery transfered
into the antenna from the feedline. And not all that much in most
cases.

> Modeling shows that short verticals don't have a high radiation
angle.
=======================
Quite correct Cecil. But modelling is hardly necessary. Common
sense and a little intuition show that the radiation patterns of
all vertical antennas of 3/8-wavelength or shorter are for
practical amateur purposes identical. In the vertical plane
patterns are similar to two touching semicircles.

The theoretical difference in pattern between 3/8 and 1/100
wavelengths is much less than the distortion due to mounting
antennas on different vehicles.

OK, I got you...I wasn't thinking about the antenna whacking a tree at 80kph (50 mph). In the US, road clearances are maintained at about 14 feet unless otherwise marked by signs. I meant that when pulling into a driveway at slower speeds and whacking the antenna, it would suffer no damage. Have you ever seen the Outbacker promotional video? If so, I can't really see how you'd call them flimsy. If you like to see the video, I could send it to you.

Strongly suggest you look at a ClearSpeech DSP speaker from www.amcominc.com or page 124 of April QST. It will get rid of your noise and all the other noise you encounter running mobile. My car is diesel so I don;t make any noise but everyone else sure does. Add noisy power lines and mobile operation can be a real challenge. The Clearspeech is a "must have" as far as I am concerned.

Dave, what the court was saying is that technological change will change the
validity of FCC rules. The Morse code exam requirement was valid at one
time, but today it is not.

You don't think that the Amateur Radio community can not lose frequency
allocations. The FCC must allocate frequency in the public interest.
How is the public interest satisfied by maintaining a non-conforming
requirement?

It has been my experience that most Radio Shack antennas come with
instructions
for adjusting the tuning for 10 Meters. I have a small, 3 foot, mag
mount
for my car and a base station vertical at home. I don't use a tuner for
either one of them. Like most mobile vertical antennas, the mag mount
depends on the car body to act as a ground plane. If you were to use it
some other way than on a car, you would need to provide the ground
plane.
The base station vertical is actually a vertical dipole and doesn't
require a ground plane. It does a fine job at just about any height.
The bandwidth was wide enough to cover the CB frequencies and the
lower 400 to 500 KHz of 10 Meters without any tuner.

But, for about the same price as a cheap mobile whip, you could probably
build a nice simple dipole. I use to have one stretched between two
trees. Just two lengths of wire and some coax. I didn't even bother
with a balun at the feed point and still never need a tuner. 15 to 20
feet of height is about all you need for a good signal..

They do every now and then make additions to the Antenna Book and that
was added in the 19th edition.

Quite simple.I've heard that a multiple reflector compensates the missing of
directors.And since I have not the space for 10 or 15-element antennas,I
thought,this is a good solution

Jason Hsu, AG4DG wrote:
"Are there any equations that calculate ground losses?"

The 19th edition of the ARRL Antenna Book does a good job starting on page 27-35 of showing how ground conditions affect surface propagation at frequencies between 2 and 30 MHz.

The question was why do ground losses increase with frequency. There are per cycle losses in nature. We have "skin effect" that increases resistivity as the square root of the frequency. For example, surface resistivity for a conductor is 3.16 x the 1 MHz value at 10 MHz.

The Austin-Cohen formula has been much used to estimte ground wave daylight signal strengths of low frequency radio waves over water since the early days of the 20th century. Austin-Cohen was concoted from experiments. Math was later applied to explain and modify it. The original formula works better than the modifications. It`s been determined that an attenuation factor of the form "-alpha d / lambda to the nth power" has theoretical justification. So, as the wavelength shortens, the signal strength declines because the quotient, which is the attenuation factor, increases. Austin-Cohen has been extrapolated.

If you want in-depth information on propagation of radio waves, Terman knows all and tells all.

Best regards, Richard Harrison, KB5WZI

5919. best length of "all band" dipole?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-26 16:40:50 UTC
From: Rudy Marcelletti <rudym@net-link.net>
Message-ID: <3abf7132$0$88187$bbae4d71@news.net-link.net>
Source record: 167492

I have seen adds for all band dipole kits fed with ladder line and the lengths all vary! What is the best general length for an "all band" dipole? By all band, I am referring to something that can cover at least 80 to 10 meters with a good tuner, 450 ohm window line, and no loading coils/traps/ resonactors/gizmos, etc. Several antennas are sold as "all band" and are about 100 to 102 feet of wire, 3 insulators and 100 feet of 450 ohm window line. Why this length? Why not the resonant length of the lowest frequency you intend to operate? Would not this work better?

And what about those code tested "Hams" who don't have knowledge of the various digital modes, ATV, satellite operation, and the list can go on and on? By your logic those code tested Hams are not "REAL Hams" either. They don't "possess the skill to operate" as you put it. What goes around comes around. If you want to conjure up some logic, like yours above, just be prepared to have it applied universally, then we shall see if the shoe fits or not.

> Which is basically what the whole discussion is about...

Amateur Radio elitism organized along the Code / No Code dividing line. You can dress up the CW elitism up anyway you like, but it's bigotry anyway you look at it.

There are no traps that are "driven" or "reflector" traps on the Cushcraft X7 triband beam--only traps on one director element at end of boom. Would arcing still occur? I don't think we have the little wasps referred to in Michigan. Maybe spiders, but most bugs spiders are after are lower than 100 feet, aren't they? Would a bad match box cause high swr on 20 and 15 but not on 10?

I will try to use a spotting scope to look at the traps. Maybe it is different problem?

Reg wrote:
"What is the conventional wisdom which dictates 1/4-wavelength radials?"

The same current flows in the surrounding ground as in the antenna. In the ground, the current from near and far converges at the tower. (vertical antenna) Loss due to high current density can be mitigated by making the surface near the tower into highly conductive ground by adding copper radials.

Experiments showed the area within 1/3-wavelength contributed the most ground loss. Being stingy with copper, this was cut to 1/4-wavelength.

A ground system with 1 ohm of loss resistance under a 10-ohm tower is about 90% efficient. That ground resistance would require on the average about 120 radials about 0.3 wavelengths long at 3 MHz.

A ground system with 10 ohms of loss resistance, as might be typical of a ground rod under the same tower, would drop the radiation efficiiency to about 17%.

So, the 1/4-wave radial system is a compromise.

Best regards, Richard Harrison, KB5WZI

James: You indicated the vehicle is a Jeep and I assume you are likely to go off road. If so, then the stainless whip antenna is your best shot. At present, I am using an Icom IC-706MKII, AH-4 coupler and whip. I have the coupler mounted on a piece of aluminum plate bolted to the luggage rack on a Suburban. There are 2 large ground straps attached to the body. I have a big ground plane with the Suburban body--something you don't have with a Jeep. You will need to tie as much metal together as you can on your vehicle. I have a ball mount on this plate also, with a 6" spring. I have been using a 102" stainless whip, and added another foot to the bottom, for a total of 10 feet, plus what ever length the feed wire is from the coupler output, about 8 inches or so. I was having problems tuning on 6 meters and thought I was having a half wave multiple problem, so added the extra foot. Turns out the antenna and coupler was reacting with a Comet SBB5 and/or Z780 dual band vhf/uhf antennas I had also mounted on the aluminum plate. I put a Comet SB10 cell look-a-like there and it works fine now on 6.

I WHACK A LOT OF TREES, BRIDGES, LIGHTS, AND DRIVE THROUGHS WITH THIS WHIP ANTENNA! It has held up for 6 months very well!

The whip antenna works very good on 20 up to 6. The coupler will "tune" down to 80 meters but the signal is very bad. I use a short Huslter mast and 75 meter resonator on this band. The coupler does not like this set up on higher bands.

40 meters is OK with the whip--but you will not be a big signal with 100 watts on this band anyway, but it will be an acceptable match for local rag chewing in the morning and mid day on this band.

20 to 6 meters are a blast. I really like 17 meters!

Take 30 feet of 18ga wire with a heavy duty alligator clip with you. Clip it to the end of the whip and toss the other end into a tree. Works real good on all bands. Lots better than just the whip! You can trail a 10 foot piece of say 28 gauge wire with you down the road too! Looks hokey though and you can lose it.

You sound like you are looking for durability and will sacrifice performance for it. You will get a bigger signal from a loaded whip (on the band it is designed for) or from a screwdriver or bugcatcher antenna, however, for your Jeep and off-roading I would recommend the whip over anything else. Take 30 feet of wire with you to throw in a tree! It will take a beating--no doubt about it. It will outlast anything else you can put on your vehicle. You can put a flag on it where it is required at dune parks and such. I would mount a ball on the left rear fender and the coupler inside on the left seat area (assuming CJ type Jeep). If you have a fiberglass top, drill a hole for the high voltage wire to go through. If rag top, sew a grommet type

hole. SGC has a drawing of a similar installation in the SGC-230 coupler manaual you can find at www.sgcworld.com

If you want to just play on 80 meters while driving down the freeway, get a big screw driver and put on a big cap hat, or build some thing like Cecil did from his junk box and win a shootout--but don't go off road with it! If you go back in the bush--take the whip and wire. You don't see anything else on a Hummer! If you should happen to do something stupid and somehow break the stainless whip, and if you are still able to, you can still hook up the wire to the ball mount and call for help!

If you want a big signal on 80--put up a full size vertical with 8 elevated radials at home and use an AL-1500 amp!

Well any fiberglass antenna with a particularily strong bulk modulus (high rigidity) will dislike being hit by debris and trees ... just one of those things.

Honestly, the ham sticks aren't too good ... but they work well enough ... and are dirt cheap

Same reason you have a 1/4 wave vertical element. You're aiming for a 50 ohm feedpoint impedance at resonance.

> you intend to operate? Would not this work better?

If we keep the SWR on 450 ohm ladder-line between 4.5:1 and 18:1, the
impedance at a current maximum point will be between 25 ohms and 100
ohms which equates to a 50 ohm SWR less than 2:1. Some lengths of
all-band dipoles are better at achieving that desired SWR range than
others. 102ft will NOT achieve that range on 75m. Modeling indicates
that a 130ft dipole at 40ft high will achieve that desired range of
450ohm SWRs on *all* HF ham bands so that's what I use. I tune my
antenna system to resonance by varying the length of the ladder-line
and don't need an antenna tuner. More information on my web page.

Rudy,
Yes, a 'resonant' length at the lowest frequency of use
would work out better than a random length would (going to
get an arguement there!). In general, the longer the
antenna, the 'better' it will work.

Rudy,

Take a look at Larry Cebik's website: www.cebik.com and read his informational notes (titled
'If I could only have one wire antenna' or something close).

L.B. did extensive modeling and shows the results: 88' plays well if you're wanting to keep its pattern close to a dipole. You may improve your understanding of how/why varying lengths get quoted by reading some of the other works on that site.

Should you decide 40-10 meters is your goal, L.B. shows the benefits to using 44' in length. Others have laid claim to this one as well. Its a great compromise for portable uses. Some additional details are there for making this a rotable dipole and a stack.

The 102' you refer to seeing relates to G5RV/Varney's well known 20 meter extended dipole that will also allow a reasonable compromise on the other bands. His original design has suffered at the hands of many 'antenna designers'. Thus, reports vary with which 'version' is used and rarely are the surroundings considered. L.B. also addresses the G5RV in easy to understand fashion.

Bests,

Patrick

jhilins,
I have no idea if the Jeep is more susceptible to RF than
other vehicles, but I'll offer this. Route all cables as far
from the 'computer' as possible. Do NOT use braid as a ground
strap, it will deteriorate in weather. Instead, use a copper
strap such as the flashing used around roofs. And make the
best mechanincal connection you can. Most problems with mobile
antennas usually come back to grounding.
The standard steel whip, or SGC's whip are useless on the
lower HF bands. They ~will~ load, but no one will hear you.
If your going to use 80 and 40 meters, invest in some kind of
loaded antenna, otherwise you will be a very frustrated camper.

5932. Egg insulator for dipole center?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-26 18:59:20 UTC
From: "Dave Cook", com
Message-ID: <ckMv6.627409$U46.19171573@news1.sttls1.wa.home.com>
Source record: 167506

I'm putting together a lightweight dipole and was thinking about using a lightweight plastic egg inslulator for the center instead of the traditional glass/porclain center insulators with the eyes on the ends. The ARRL antenna book says that strain insulators "may" be used for center insulators, but doesn't elaborate. I was wondering if there are any issues with a) having the dipole wires actually cross over slightly in the center, and b) using a plastic insulator at the feedpoint.

Michael Edelman, KE8YY wrote:
"Same reason you have a 1/4 wave vertical element. You`re aiming for a 50-ohm feedpoint impedance at resonance,"

I think Reg has a program called "Earthies" to help with the analysis needed for entanglements with the earth. I should have used it before my last posting. A 10-ohm antenna with a 10-ohm ground would probably have lost about 1/2 its energy in the ground and thus had an efficiency of 50% or thereabouts. I wrote 17%.

Reg can make the point that as radials come near the ground from above, the wave`s velocity on the radial is slowed by ground loss just as ground loss puts a drag on a traveling wave far from an antenna. The slowed wave at the earth`s surface traveling away from an antenna tilts the wave forward as if it were literally dragging its feed on the earth.

So, in a radial near the earth`s surface whether buried or not , the wave is slowed from its free space velocity. This results in a shorter radial travel distance in the copper to reach 90-degrees of phase rotation (1/4-wavelength). So, A radial that is 1/4-wavelength in free space is actually longer than a 1/4 wave near the surface of the earth and is no longer resonant if that were the intention, or not.

Also, the 1/4-wave vertical is half of a 1/2-wave dipole (its image is in the ground) so its drivepoint resistance is 1/2 that of the dipole or about 36 ohms. 50-ohm coax is not an automatic match.

This will sound a bit bizarre, but please bear with me.

I recall going to a hamfest in Indianapolis (Marion County Fairgrounds) about 2 years ago. I saw something quite weird. It was a large ROUND antenna. The maker claimed you could lay it flat on the ground or hang it in an attic. When they demonstrated it (with a radio attached) they had it lying on the ground. Worked quite well.

I do recall they had a website. But, I've lost the address and I have no idea what the antenna was called. Has anyone heard of this? Seen their website?

It looked like a giant hula-hoop and was quite thick.

Thanks

Ted, kb9rpd

Plastic works just fine; in fact, some other ham here in Burlington, North Carolina even makes center insulators out of 1/4 sheet plastic. But his don't have the wires cross.

Nice try, Peter. j/1 is j. 1/j is -j. They're not equal. Either of
them squared is equal to -1. In fact, they're the two roots of -1,
but again, they're not equal, any more than the two roots of
four are equal. Perhaps you misunderstood Dr. Nahtan. Maybe
you should work on your code.

This is true only if you do the arithmetic inside the brackets first.
Otherwise you are calculating two different square roots and
calling them equal.

> Assume that j=sqrt(-1) and substitute
> j/1 = 1/j

This is a false statement since j does not equal -j. All the rest,
based on this transparent falsity is wrong, too.

I agree! Let them argue! That's what the tuner is for. I don't have the time to fiddle with different lengths of ladder line or make up a relay box like Cecil has, and besides, I am mainly interested in portable wire antennas. Sounds like a good old fashioned tried and true 135 foot dipole fed with 450 line and a decent tuner like an MFJ-986 should be just fine on 80 to 10 meters, double that for 160 meters, or short and work over ground as Marconi. I guess I must have been thinking G5RV and that's where I came up with the 102 feet.

All your problems associated with location of loading coil in a short vertical antenna, mobile or in your back yard, can be solved by downloading program LOADCOIL from website below.

Optimum loading coil location, whether it be somewhere in the antenna or antenna tuner, depends on ground loss resistance and on loading coil Q.

It is in any case of no great consequence. Just get the biggest and fattest coil as possible into the antenna.

Or download new program TOPHAT1 from website below. This will show that a top hat on a short vertical can be several dB better than any antenna of the same overall height with a loading coil 1/2-way or 2/3rds way up the antenna.

Of course, if you have an antenna approaching 1/8th or 1/4-wave in height, there's little or nothing to be gained by either capacitance or coil loading at any height. Just tune it up and away you go !

Download LOADCOIL now. Another way of looking at the same thing is available by downloading program VERTLOAD. Yet another way of analysing performance is available with HELICAL3 which deals with loading coils at the bottom only or with coils extending all the way from bottom to top.

The 1978 ARRL Antenna Anthology, pp. 94-98, shows such an antenna -- A 40-Meter DDRR Antenna, consisting of a 1/4 wavelength element grounded at one end and wound into a single-turn coil, a few conductors diameters above the ground.

I used one that way for years. The only issue is UV protection of the exposed coax dielectric over a long period, which doesn't apply in your case. Presently, I am using a portion of a guy wire as a dipole by attaching the coax across one of the egg insulators.

Neither of the issues you raise is a problem, provided that the dipole is roughly an odd number of half wavelengths long. At these lengths, the impedance at the feedpoint is low, so it's very tolerant of any shunt capacitance or resistance. You can use just about any halfway reasonable material and configuration for an insulator. Unplated PC board material, PVC, even a plastic curtain ring, wood dowel, or piece of Nylon twine are ok. (I've used a curtain ring for a very lightweight dipole. Epoxy-glass PC board material is good if the antenna will be used for long in the sun, since it's not made as brittle by UV as most plastics.) If, on the other hand, the antenna is about an even number of half wavelengths long or is considerably shorter than a half wavelength, the center impedance is very high, and the center insulator can have an effect. In these cases, you should use a low loss material with decent spacing between conductors. Low loss capacitance won't hurt anything, but you need to avoid any leakage path or lossy C when the feedpoint impedance is high.

Sounds like the CTHA (contra-wound toroidal helical antenna). You can see some pictures at http://www.antennex.com/shack/Jan00/hawks.htm, and a web search for CTHA will yield other URLs. I have no doubt that it will radiate. But just what fraction of the applied power is radiated isn't something the manufacturer has been willing or able to tell.

I can understand you going with what you have been told, but you have
been told wrong. It is doubtful if you will get enough gain with the 3
reflectors over just one to notice. Almost no comercial antennas are
using the 3 reflectors any more.

Source record: 167423

Best can be deifned in many ways. The 100 to 105 feet for the g5rv is
'best' if you want an antenna that will have low swr over the most ham
bands. The 120 to 135 feet of a dipole will be 'best' as far as the
signal strength.
There are some other antennas that will be 'best' depending on who is
doing the talking. Best bet is around 130 feet or cut to the frequency
you most use on 80 meters and feed it with about that much open wire.

One 'best' was to take about 265 feet of wire and cut it in the middle.
Suport the ends as high as possiable and put the other ends at the
tuner. Then make a feedline out of part of it spaced at 3 to 6 inches
and support the 'center' as far away and as high as possiable.

That isn't true.

The difference betweeen a single reflector and multiple relectors
(trigonal) is nearly immeasurable.

The gain of a yagi is a function of boom length, and once you have one
reflector you pretty well have it all handled at that end of the
antenna.

Hi Ted,

What were they comparing it against? Antennas very close to the ground are very inefficient, there is no way around that.

There are a lot of false claims and misinformation to the contrary, but the fact is always that nearly all applied power is eaten-up in losses. That true for the DDRR, the CTA, the CFA, and all these magical antennas.

Save your money, and stay away from gimmicks.

Cross-posted to: rec.radio.amateur,rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.swap,rec.autos.makers.jeep+willys,rec.ham-radio.swap

Doc,

It amazes me that the tuner/whip combinations garner any sales at all. Of course, it is just MHO, BUT that opinion is based on many years of HF mobile study, installation, and mistakes. In some cases, a hamstick will outperform those things--and a hamstick is just about the worst thing on the lower bands. I wouldn't waste my time, nor my hard earned cash, on those things.

It is an unfortunate thing that some people *really* believe that a "tuner" actually "tunes" an antenna. I had such a conversation with a supposedly knowledgable Extra class last week! When I pointed out that tuners don't "tune" the antenna, he confidently assured me that a certain brand of "tuner" both (quote) "physically and electrically" tune the whip! PHOOEY! I hear sub-standard mobiles on the air all the time. They are often down in the mud, unreadable, or just not even *there*. Yet their owners swear by the "great" performance their tuner/whip combo is giving, how "good" their hamstick (dummy load on a stick) is, and my question is always: Compared to WHAT? Put 'em in field trials, run field strength tests against bugcatchers and screwdrivers. See the superior field strength of competitive, high Q, RESONANT antennas--it'll make ya sick! I guarantee your tuner/whip or hamstick will get MASHED in a field trial.

Now, having thrown off on the tuners, etc, let me say this: Certainly, there are times when it is not feasible to use higher efficiency antennas. The spouse threatens bodily harm if you drill holes in the new car, or there is no way to attach a big antenna. You do what you have to with what you can. And that is understandable. But if you are out for the best signal you can obtain, it takes a BIG, UGLY antenna to do the job.

5963. Radiation Resistance

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-27 01:09:56 UTC
From: mover123@webtv.net
Message-ID: <3241-3ABFE864-9@storefull-245.iap.bryant.webtv.net>
Source record: 167443

All,

I am new to this group - first post. Please accept my apology if this has already been covered ad nauseum.

In the amateur radio literature, I have read that (paraphrasing) "Radiation resistance varies from point to point along the antenna. For example, if at some point the voltage and current are in phase, and the current is 1A and the voltage is 75V, the radiation resistance at that point is 75 Ohms".

My problem with this statement is that I am used to thinking of impedance as a property associated with a PAIR of terminals. What is meant by 75V a some point in the antenna? The radiation resistance defined at the center of a dipole makes perfect sense to me. Is this just sloppy wordsmanship in the literature, or what?

Thanks, Paul

5964. Re: Imaginary Resistance... Dissipationless Resistance... and all that....

Newsgroup: rec.radio.amateur.antenna

Message-ID: <99oplmfip1@slb6.atl.mindspring.net>
Source record: 167437

Donaly:

Heh, heh... Nope it's not my code that's the problem.

Actually the "proof" presented by the good Dr. on 15m CW was, quite good at least I thought so at first.

But after the "fever" of trying to copy Dr. Nahatan's rough hand sent CW through bad QRM died down, I did finally figure out what the flaw in his proof was...

Can you spot it?

I'll share it with y'all later.

And so... I cancelled my "order" for diamond dust! Heh, heh.

That all being said, I still want to know... what then is "imaginary resistance"?

Imaginary resistance jR is a perfectly valid concept as far as I can see. Why not?

It is certainly not "dissipationless" resistance since the current and voltage through and across jR are exactly 90 degrees out of phase and so the power dissipated in it is itself "imaginary".

But is jR an energy storage mechanism like inductive reactance j*2*pi*f*L, and that other reactance?

If not then... What?

We may have difficulty buying jR's from the local electronic parts jobber, but that does not mean that imaginary resistances don't exist. Or that they can't be constructed. In fact I have discovered a "neat" construction for an imaginary resistor.

Now then... what if an antenna had a radiation resistance that was imaginary?

What if a transmission line had a surge resistance that was imaginary?

Surely imaginary resistance is a more viable concept than that dang foolery called a "dissipationless resistance". No?

Think about it...

I'll share the flaw in Dr. Nehoc's proof in a subsequent posting.

Best Regards,

-Peter

Well actually, they're the sole protector of ARRL's singulara
interests, first, then if there's anything left, US hams as a group
might get a little attention.
Back in the days of HPM it was as you say. But HPM is long gone.

5967. Re: Imaginary Resistance... Dissipationless Resistance... and all that....

Donaly:

OK, OK... you got it correct.

I didn't read your analysis thoroughly the first time I replied, I didn't notice the leading carrets... >>.

Yes, at the point of taking square roots, the good Dr. should have put plus and minus signs on each side. Since the sqrt operation does not produce a unique result. The square root operation produces two unique results, and on each side of the equation. Then the development of the proof would need to take four different tracks from that point and the "valid" path chosen. Heh, heh. Good work!

i.e.

As you pointed out...

The proof should have read...

+- sqrt(-1/1) = +- sqrt(1/-1)

and then... the four different cases resulting from this "equality" would need to be sorted out properly...

That being said...

I again ask...

What about "imaginary resistance" jR, is that not a valid concept?

Best,

-Peter K1PO

Jeez Jerry, you're confusing the heck out of me.

Didn't you say a couple of weeks ago when someone asked about wiring a CB to: wire the hot side to the battery and the neg side to a nearby bare metal groud?

I had thought of wiring my CB direct to the battery (pos & neg, both fused) and then had second thoughts after reading that post of yours.

Now I've interpretted your post below to say pos and neg to battery.

I've made light ones from plastic coathanger material. I cut off little
2-3 inch strips, and then drill or melt holes in the ends. Worked fine.
You can carry them in your pocket like pencil stubs. Good for camping.

I think I'd rather have a metal radio shack one though myself. Mainly for the lightning aspect. If you take a hit on it, the mast will be the lightning rod to ground. A plastic rod will be a disaster looking to happen unless you have real thick wires running down it. Only if there were an rf reason to use a non conductive mast would I consider that, or maybe camping etc. At home , you will be better of with the metal mast if you are in a lightning area. I took a hit on mine once. Being as I had no damage to any antenna or feedline at all, that tells me the mast itself did 95% of the dirty work directing the strike to ground. "I have it grounded well at the base". if the coax had directed the strike it would have been punctured down near the base somewhere. it wasn't. The mast itself did it all nearly as it's about a foot higher than the feedpoint of the dipole antennas. MK

Can lose? I don't think that amateur radio will lose any of its HF
allocations though we might see 40m realigned in future.

We don't have a "non-conforming requirement". There is still a 5wpm
requirement for HF access. I don't think you should waste time blowing
smoke up the asses of those congregated in this newsgroup. Mount your
soapbox and spout your homemade semi-legalistic rantings where they
might make some difference. Here your stuff is just cheerleading.

You are clearly uninformed as to who is forming opinions
as to the rational and need for code testing. Many, including
myself, have "been there, done that" as to passing the
code test at speeds greater than 5 wpm. Not all those
opposed to continued code testing are so "uniformed"
as you think.

In the absense of any contradicting comments,
the FCC sure seems to think so too. I haven't read
one FCC comment that put any rational into
why code should be kept as a test...with the singular
exception being that for now, it still is a treaty
requirement.

Paul wrote:
"My problem with this statement is that I am used to thinking of
imedance as a property associated with a pair of terminals."

Paul has it right. Impedance is associated with a pair of terminals.

Most antennas are of the standing wave type. These have open circuits at their tip ends. When the traveling wave arrives at the tip end of the antenna there is no where for current to go except to return to the sending terminal of the antenna. Interference between the forward and reflected waves on the antenna produces an impedance variation from maximum at the open-circuit tip end to minimum back !/4-wave from the tip end. The feedline can be attached at the point on the antenna which matches the feedline. I don`t know what your author wrote but he may have made the mistake I made in writing the above.

If an unbalanced antenna was the topic discussed, it may be assumed that the author expected the reader to know the voltage or impedance was referenced to ground. If a balanced antenna was the topic, then the author was implying equal distances in opposite directions from a center feedpoint.

How this impedance selection process is made with a balanced antenna may be seen on page 18-5 of the 19th edition of the ARRL Antenna Book where the "Delta Match" is covered.

The same process can be used with an unbalanced antenna where it is called shunt feeding the antenna worked against a ground system. I was most disappointed to find no index listing for "shunt feed" in the ARRL Antenna Book index.

Best regards, Richard Harrison, KB5WZI

5981. Frustrating dipole construction

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-27 02:56:23 UTC
From: ke4qkn@aol.com
Message-ID: <20010326215623.13235.00001743@ng-fi1.aol.com>
Source record: 167455

Tried to build a nice 1/2 wave dipole today for 10m and could not get the SWR below 2:1. Never had this problem before, thought I might have forgotten to do something......

The center is a Van Gordon 1:1 HI-Q balun. Measured 8 ft 3" of wire for each leg, plus an additional foot: 6" to work with in the center, 6" to work with on the end. Used 14 ga stranded THHN wire. Soldered the ends to the middle, made 5 loops through the lug, used end insulators with 5 loops on each end. Hung it up about 10ft off the ground in the driveway to test it before hanging it, and like I said, could NOT get the swr below 2:1. I use an MFJ antenna analyzer and the lowest SWR I could get on this thing was at about 24.5 mhz, it dipped down to 1.7:1.

Got frustrated, took it apart started over. Same problem. Second time I used 18 ga stranded wire.

All my soldering connections were solid, and I used about 5 different pieces of coax, so I know it was not a coax problem. I also moved it to 3 or 4 different locations for testing, with the same results. I even tried hanging it as an inverted V!!!! Nothing seemed to work.

I tested the balun with a VOM and there was no short. Is there any way I could have gotten a "bad" balun? Like I said this is the same construction technique I have used for making dozens of dipoles and I have never had this problem before.

Flame away.

Frustrated, KE4QKN/AE

An antenna is implicitly a two wire circuit, with one half of it immaterial,
IE the displacement current through space which completes the circuit
is the second "wire". So the potential discussed is between this point on
the wire and the rest of the universe.

It's a bit hard to put a test probe on the rest of the universe, because it
is large, and there are phase effects across such a large distributed
structure (just using a ground won't do, particularly if the antenna is
being operated well away from a ground point, IE in free space). So this
concept is mainly of use for analytical purposes rather than for real world
measurements.

But if you broke the antenna at this point, and somehow maintained the
same current flow (say by inserting an ideal current source), then you'd
measure 75 volts between the two parts when 1 amp was being driven
across the break by the source. This is what you have at a dipole feedpoint.
The two parts of the antenna become your test probes, connecting to the
rest of the universe and completing the circuit.

Note that you can't just break the wire without adding the current source.
Then there'd be zero current flow, no generated fields to complete the circuit,
and any voltage you measured would be irrelevant to the actual behavior of
the intact antenna.

I'm strongly considering the purchase of an Electraslide screwdriver
made by Clay Emert of the El Paso Amateur Radio club:

http://www.dzn.com/w5es/ELECTRO.HTM

Has anyone used one and if so could I get an opinion?

I will be using mine in a Chrysler Mini-van with an Icom 706MKII-G.

Also, it is apparently available with either a copper or an aluminum
bottom tube. The aluminium of course is much lighter. Any comments
on whether one or the other is preferable?

Thanks,

Dave Alden KB8VJD

No, the braided (or whatever) ground strap I was referring to goes between the radio's chassis and the Jeep body or chassis. It's just that a braided ground strap provides not only a good DC ground, but a good RF ground too. The positive side still goes to directly to the battery through an inline fuse. The rule-of-thumb is that the ground wire should go to the closest possible electrical ground. The ground wire can either be the black wire, or simply a ground-wire (or braided ground wire) connected between the radio's chassis (like a cabinet screw) and the Jeep's body or chassis. HTH!

Cortland, KA5S wrote:'"If the antenna is located near a noise source whose field is predominantly electric, then it can indeed reduce that noise. But by the time you get some distance away from a radiator, the electric and magnetic components of the field have reached a ratio of 377 to 1 for both noise and the desired signals."

Nice summary! That`s what I think, too. Once the loop is in the far field of noise sources it still has the same advantage of an unshielded loop as it can be oriented to null out noise perpendicular to the loop just as an unshielded loop can.

Thanks for performing the loop experiment. You found that a signal could still be received by a loop with a properly situated shield. I`m sure MFJ has tried their product before offering it for sale. I`ve bought a couple of items from MFJ and they both worked well. There may be better similar products, I just don`t know. I make no endorsement and don`t disparage their products either. I don`t know of any MFJ product which defies scientific justification.

Best regards, Richard Harrison, KB5WZI

Assuming the SWR was higher on each side of 24.5 MHz, that means the
antenna impedance at resonance is either 29 ohms or 85 ohms. Antennas
don't have to be 50 ohms at resonance. A perfectly resonant 1/2WL dipole
in free space would have a 50 ohm SWR of 1.5:1

Eafter = C1 * (V^2) / 4 PLUS C2 * (V^2) / 4

You left out the second cap. Solving:
since C2 = C1,
Eafter = C1*(V^2)/4 + C1*(V^2)/4
Therefore Eafter = C1*(V^2)/2

Simple algebra does work on this, despite what was
indicated in an earlier post. Nevertheless the theory
discussed was valuable.

It's called an inverter. I picked one up not too long ago at Pep Boys (auto parts & accessories) for a good price. Audiovox brand, model ADC150, rated for 150 watts continuous power. Works great! I use it to run my notebook computer when we travel and don't have AC power available. Very handy item.

I have a "shorty" G5RV (40-10 meters, 1/2 the size of the full length model) which I picked up at the TRW ham swap meet a few months back. It's up not quite two stories up and it does a fine job. Used it on 10m in November for the Sweepstakes and managed to log a couple of sheets worth of contacts (more than I planned on, as a "casual" participant). I was duly impressed!

>
> What were they comparing it against? Antennas very close to the ground
> are very inefficient, there is no way around that.

I am wondering if ther is a way around it. The ground forms a boundary a (poor one), but it could be made to look like a good one where the Voltage will be normal to or zero at the boundary, (the vertical Antenna) and the magnetic field will be parrallel to or zero at. (the loop antenna)

The 'zero at' the boundary condition often occurs where there are other boundaries that produce a sitution where a mode can be set up, such as the inside of a waveguide or a cavity. In free space in the abscence of large buildings to form boundaries it is likely that the 'zero at' condition will not occur generally, thus one might anticipate that large currents due to a wave would pass at the boundary.
If a suitable transducer is placed at the boundary then the currents may be detected. i.e. the slot cut into the narrow wall of a waveguide, the current lines are cut and the slot radiates. By reciprocity a wave across the slot excites the waveguide. An Antenna at ground level might be capable, if designed carefully, of duplicating this mode of detection.

Just because it ain't been done it doesn't mean that it can't be done.

In general I would agree with that Tom.
However, when a wave terminates at the ground where does the current that forms the boundary flow?

Who a few years ago would have anticipated Cave Radio?

That is true Ian, I have been in Hospital for a triple bye pass that didn't work out as well as it might, so I have spent a good number of years closeted at home. On Sunday I managed to go to Blackwell's in Oxford where I did find a couple of tomes that lightly touched on the subject; one a translation from the French price £55 and one other book price £74. I'm afraid that at those prices I will not be reading them, much as I would like to have them in my collection. I would not expect a request to our local library to be fruitful, besides they are the sorts of books that one retains for future reference. Neither book touched directly upon this low end of the spectrum.

> The reality is that for a few pounds or dollars, you can make a highly

Just how stable is the calibration?
Of what magnitude of noise temperature are you speaking?
Will any of the sources make 10^8 K?
I want to be sure to bracket the temperatures of interest, an extrapolated
result is probaly worthless beyond being an indicator.

> The only difference between an amateur and a professional diode noise
> source is likely to be that the professional source has a flatter
> calibration curve, and goes to higher frequencies.

At the moment I am interested in going down. This site is in a dip. It would
be OK for Moon-Bounce, but I feel physically incapable of constructing a
suitable antenna for that and besides the number of operating hours a month
are too few to keep me out of mischief. Therfore I have turned my eyes
towards the low end of the band wher hopefully being in a hollow will have
less effect. the remaining challenge down here seems to be 136 kHz so I am
reconoitering the territory. It seems that I will be a bit short of
co-experimenters.

> use any more.

(My first experience of this type of noise source was in 1957, noise power
was calulated from the reading on an ameter in line with the directly heated
filament. It was of German origin, not surprising as I was then in Germany.
;) At about this time I encountered the Schomandl phase locked frequency
standard, each section had to be manually tuned; the state of tune indicated
by a magic eye tuning indicator. All valves/tubes.)

That is a bit of information that I have missed during my confinement.
Due to my circumstances most of my re-awakened interest will neccassarily
need to be confined to theoretical work. A I can't afford equipment, B if
any Aerial construction is require I need to be absolutely certain before
commencing work that it will have some measure of success the physical
effort involved will take me a week where a fit person might spend an hour.
There are no willing local Hams that would errect an antenna for me. C I
can't get about to chase components.

> >However the construction of Hot and cold
> >loads can be a kitchen table exercise which many Hams could adequately

> >accomplish.

Once I get started I would be OK. I have a Palomar R-X Noise Bridge which will provide some noise, but I have doubts about the calibration and stability of that noise source and I think that the attainable noise temperature is too low for the bottom end at 136 kHz.

> Not unless your kitchen has hot and cold running liquid nitrogen :)

That is not such a pipe dream. (sic) LiN is available in small quaties if you have a suitable Dewar. BOC have a plant near us for the M&S depot presumably I could get some there, however LiN temperatures are not required for use at the low end of the SW bands, on the contary what I need is a stable high temperature noise source and a load at ambient temperature can be the cold load.

> Seriously, it is by no means as easy as you suggest, not if you're going
> to do a really accurate job. If you choose to use conveniently
> accessible temperatures, the temperature baseline is short and you run
> into trouble with making accurate dB measurements.

Unfortunately Ian I am only too well aware of that problem, I have been turning the problem over in my mind for a few years. I have devloped a method of calibrating signal level in an Rx to very fine limits, I checked it out extensively at 2,295 MHz and it is a winner. I want to adapt the method so that a small additional circuitary added to a communications receiver which is under the control of the processor that is built into most of them these days so that an accurately calibrated digital display of received signal level may be built in. Imagine the change that this could make to contests. (No more gratuitous 599 to all and sundry). With the development of reliable methods of measuring ERP accurate models of the propogation characteristics could be made from the results of contests. The dynamics of propogation could be better studied, some of the short term changes that occur in propogation at HF might be studied. This would at least give a magnitude study whilst better methods to recover the phase data are developed.

> On the other hand, if
> you do have access to solid CO2 or liquid nitrogen, you run into
> problems with changing impedance of loads, and corrections for noise
> contributions from the parts of the system that are not at the same
> temperature as the reference load. In other words, it is not a simple
> job in practice.

Believe me I have done it professionally I know exactly what you mean and I am quite happy that at 2,295 MHz I became very competent with these proceedures and handling LiN.
We had a Dewar of LiN that was 25 feet tall and several feet in diameter. In order to measure the level we placed one foot on a pad of material that changed its resistance with the applied pressure. We also used the LiN for cooling the MASER down below the inverison temperature so that we could quickly (8 hour) get the Helium Refrigerator going) They have better methods

now I understand.
CO2 in conjunction with To would not give a sufficiently long baseline for work at the lower frequencies. The longer the base line the better the results, though a baseline adjacent to the temperatures at which the system is to work will give satisfactory results.

The first step to understanding is curiosity, the second investigation, If I prod it, does it bite. The third stage is formal description, and the final stage is prediction.

If you were generous of spirit instead of ridicule you might offer some sound advice and facts, then all of the subscribers to this news group might learn something instead of having to read through your baiting posts.
I have tried to go easy on you so far Tom, but it seems to me that if your claims of an extensive AE Farm are true you have far too much money and not enough real curiosity.
You have missed what the intellectual giants understood so well.
I think that Isaac Newton summed it up when he said, "I do not know what I may appear to the world, but to myself I seem to have been only a boy playing on the seashore, and diverting myself in now and then finding a smoother pebble or a prettier shell than ordinary, whilst the great ocean of truth lay all undiscovered before me."

But the input resistance of a 1/4-wave resonant vertical is not 50
ohms - it is only 36.

Rudy;
Beware the idea of using the tube as a ground plane. What you have in mind here is a coaxial antenna; a center fed vertical dipole. Both ends of that dipole must be connceted to nothing, but insulators... not to the bike's frame.
If the tubing were long enough, you could attach a quarter wave sleeve (sometimes called a decoupling sleeve), to that support at its top, where the antenna would be mounted. With the bottom end of that sleeve touching nothing conductive! The closest thing that I can think of to use as an example is an Isopole, with the bottom cone removed and with the upper cone untapered.
This type of antenna was used on the old Ma Bell (yea, does go back quite'a ways) VHF Hi-Band Mobile Phones. There are also some cell phone antennas using an "elvated feed", but with all the streamled covering, it's hard to see.

Hello, go with a screwdriver antenna, it does not need a tuner...its big, its ugly, but it beats everything else, that I've tried. Hamsticks work soso above 40m, but for 75 go with the screwdriver. Ground the rig to nearest chassis ground, just grounding thru the coax shield is not good enough. It will work some without it but will work better with chassis ground. I've used a 706 for a couple of years and have learned the importance of good grounds and good antennas. On the bugcatcher, they work fine, but everytime you want to change frequency you have to stop and move the jumper. Hope this helps...AL

Hello,

Some thoughts...

First, I believe that the extra wire in the dipole, about a
foot, is adding to the antennas length, thus making it resonate
at the 24.5 MHz point. Check your math and you will see that
468/24.5= aprox 19ft. That is what you have with the extra
foot of wire that you had included in the original design.

A foot or so of wire at 28 MHz is a lot.

A couple of other points. You mention that you used
"five loops through the lug" what does that mean? If you
looped the antenna wire around something, that makes
the looped wire into a coil that is probably affecting the
resonate frequency also. Take out the loops. The solder
connections should be strong enough to take the stress
without looping the antenna wire.

Stranded wire will also make the antenna look longer
electrically as will insulated wire.

So... if you remove the loops, and the extra wire, the antenna
should resonate at ten meters instead of at twelve meters. If
you
can achieve the 1.7:1 ratio at say, 28.4 MHz, then it should be
good to use. Now then, we probably could debate the actual
SWR reading, but 1.7:1 is OK and very usable. There may be
environmental factors that keep the antenna from exhibiting a
1:1 ratio. I remember the first time that I tried to get a ten
meter
antenna to the magic 1:1. Took hours, and no appreciable
difference in performance. May be that the ratio will lower
when the antenna is raised to it's operating height. If not
don't stress. Just use it!

Hi Folks,

I see in an advertisement from Waters and Stanton in the UK that one of the company owners, Jeff Stanton, has designed an 3.5Mhz dipole that also works on 40 and 20m. It seems to be about 50ft total size too.

Anyone with similar designs on the web anywhere?

Cheers.

Leigh....M5GWH, currently looking at sm0vpo's designs.

Question: Do not moving, sliding, contacts create noise themselves? And
at 70 plus, it's probably just floating in the slip stream of air flowing
under the chassis. Probably fine though to dissipate static when you
enter/exit the vehicle, or hand the toll taker his (or her) due.
We do still have toll roads out east. :(

Another source of static at high speed is caused by the antenna passing
through the air. The ball at the top is intended to reduce the discharge
by getting rid of the sharp point at the antenna's tip. Sharp points
concentrate the charge and raise the noise level.

6012. Looking for Comments on Open Sleeve Dipole Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-27 12:56:14 UTC
From: kelly@dvol
Message-ID: <3ac08c8e.221362@news2.dvol.com>
Source record: 167384

I ran across an interesting multiband HF dipole antenna in Bill Orr's "W6ASI HF Antenna Handbook", the open sleeve dipole on pp 4-29. Apparently it's an old design going back around 30 years and there have been a few scattered articles on it in QST, older ARRL Antenna Handbooks and CQ over the years which I missed. I understsnd that HyGain and Force12 have used the open sleeve feed concept in a couple of their products. A web search turned up scant information on the subject.
>
The design strikes me as a better idea than the usual G5RV and trap dipoles for 2-3 band applications but for some reason the antenna has gotten very little attention in ham circles. I'm thrashing for a decent coax-fed 40/20 dipole for Field Day and would like to have comments on the design and construction of open sleeve wire dipoles from any users and/or the antenna gurus who hang out hereabouts - I'm particularly interested in understanding the limitations of the design.

>just as an unshielded loop can.

Nice but not true.

At a distance of about 1/10th of a wavelength from a small antenna, the field impedance reverses.

The loop becomes electric field dominant, and a small dipole magnetic field dominant.

All the shield does is help balance the antenna if the antenna has a balance problem....nothing more.

If the shield is improperly installed, then it will help UN-balance the antenna.

My statement wasn't quite true.

Vertical antennas near earth can be quite efficient, nearly 100%. It
does require a good overall design.

Very low height (in terms of wavelength) or electrically very small
antennas are almost always very inefficient. Especially when placed
near earth without a large ground system.

A loop antenna isn't all that efficient unless it is at least .1 wl
diameter.

They are especially poor, like all antennas, when horizontally
polarized and placed very near earth.

Slanted radials will take care of that but I have another question.
Taking a lesson from an off-center fed dipole, if we make the
horizontal radials shorter than 1/4WL and the vertical radiator
longer than 1/4WL, can we find a 50+jX ohm point? (where the
reactance can be neutralized with a series cap) I've been meaning
to model that configuration but day-trading has soaked up my time.

"Wirebook III" says "for less than full power". Why not use their
stocking number #554 - #14 wire "for maximum power". That's what
I use.

Frustrated,
As already said, the antenna sounds like it's too long. The formula gives you a 'ball park' length, not an exact one, and it's usually just a 'tad' too long ('tad' = techspeak for just a little bit). If the final mounting height is higher than where your testing the antenna, the SWR will change when your finished. But, it shouldn't be completely out of reason. Have fun...

>Thanks, Paul

Hi Paul,

Radiation resistance is mostly useless, by itself it won't tell you a thing. That's mostly because it has several common uses or definitions, all of which mean something different.

The exception is if someone carefully defines how it was measured.

My point is you have to be VERY careful how you use radiation resistance. It is probably the single most misused term when discussing antenna. Radiation resistance is the source of some very popular misconceptions.

Radiation resistance can be the terminal impedance of an antenna or antenna system, it can be the resistance at a current loop, it can be the resistance at a specified point, or it can be defined many other ways. Unless you fully understand what it all means, it is best to simply avoid using it!

In the case you describe, it seems clear they are speaking of the resistance that would appears when the antenna is "broken" and fed at any random point they choose. This is ONE definition, properly called the "feedpoint" or "terminal" radiation resistance.

The loop radiation resistance (the resistance that would be measured at the middle of the current maxima) might be quite different. The IRE definition that compares the effective current causing the radiation to the total power radiated is another definition.

That is not what I had in mind. Simply mount the Diamond dual band antenna he already has to the appropriate mount connected to the frame of the bike. The more metal under the antenna the better--just like on a car. That is why bigger vehicles generally have a bigger signal, all other things being equal. That is why simply placing your HT on a vehicle improves performance. If the antenna is not going to use the metal of the bike for the return path, as in a J-pole, then by all means it must be isolated from it and put up as high as possible. However, if a railing mount is used on a bike tube, then the most metal that can be electrically bonded to the mount should be. My rubber duck mounted on an approximately 5" x 14" aluminum luggage rack works a lot better than when it s mounted on the HT!

I've always felt that what is important about religious texts is
not what they say about the physical, but what they say about the
metaphysical. Unfortunately, some physicists like to talk about
the metaphysical, too, with about the same validity as a shaman
discussing antenna theory. The IEEE dictionary, at its best,
is neither a religious text nor a physics text. It merely
defines words as the editors think most engineers use them. If
you think the definitions are wrong, complain to the engineers.

Our antena has a 7 foot turning radius and is a multi-band mini quad (new design) for 10-15-20m.

It is expensive, however, it is easy to erect (8 bolts, 4 clamps and mount) and requires little if any tuning.

That singular exception makes HF morse testing the law of the land, Bill
so it must have some bearing. That is certainly more than comes from a
homemade lawyer quoting from a court case between a commercial
television network and a national political party. Larry's chants of
his new age mantra are a bit premature.

Well, if you're making five loops at each end, you're making it an awful lot of trouble to shorten the antenna. Why don't you just make a single loop, and then shorten the antenna an inch or so at a time for each leg. Eventually, the resonance should move into the ten meter band.

The two matters have very little to do with each other, Bill, no matter how much you might wish they did. Why can't our "I-found-a-law-book-under-a-tree" expert cite a case involving amateur radio? Could it be because there aren't any such cases?

It doesn't sound like you are doing anything wrong and it sounds like
the
results are correct.

A dipole, cut to the correct length and spaced 1/2 wavelength above
ground,
should have a feed impedance of around 72 ohms. Using a 50 ohm feed,
this
would give you a SWR of about 1.5:1. You shouldn't expect any better
than
this. The fact that it shows 1.7:1 at 24.5 mhz tells me that the antenna
is a little to long and needs some pruning. When cut to the proper
length

you should have a 2:1 SWR bandwidth of about 1 to 1.5 MHz. The bigger the
wire, or the "fatter" you make the elements look, the wider the
bandwidth.

If you place the center of the dipole at 1/2 wavelangth above ground
and then bring the ends towards ground, like a Inverted-V, the feed
impedance will drop. It is possible to get it to near 50 ohms for a
1.2:1 SWR, or better. I use a home made trap dipole in a Inverted-V
fashion for 40/20/15/10 meters and get around a 1.1:1 - 1.2:1 SWR on
the all of the design center frequencies. The 2:1 SWR bandwidth is
sufficient on all the bands such that I have no need for a tuner.

There's a kind of heat-shrink tubing especially for encapsulation. It has a liner of a plastic that melts and fills the cavities and squeezes out the ends of the shrunk tubing. I'ts probably a little more expensive, but it would give better waterproofing.

Balderdash. Commercial rules have zero applicabilty to amateur radio.

6043. Re: TUNER FOR THE AM BCB

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-27 15:29:15 UTC
From: richardharrison@webtv.net
Message-ID: <2444-3AC0B1CB-227@storefull-111.iap.bryant.webtv.net>
Source record: 167417

Marvin Rosen wrote:

"Would it be practical / possible to make an artificial ground (tuner) for am bcb for receiver experimentation?"

The purpose of a groundwire tuner is to neutralize the reactance of the wire. At high frequencies the reactance can be large.

At 600 KHz, the wavelength is 1640 feet. A 20-ft ground wire is of no practical significance as impedance goes. Inductance depends on twists, turns, size, and proximity to objects, but may run about 0.3 microhenry / foot. 20 feet would total about 6 microhenries. this has a reactance of about 22 ohms at 600 KHz. To tune-out such a low impedance out requires about .01 microfarads, in series.

The short answer is that in most cases a groundwire tuner is not worthwhile in the mediumwave band.

Best regards, Richard Harrison, KB5WZI

Essentially by *doing* measurements and *using* the theory in support of
that.

There is lots of information on the web, for example in the 432MHz and
Above Moonbounce Newsletter archives at www.nitehawk.com/rasmit/ and the
DUBUS magazine archives (www.dubus.org). There are also many years of
recorded noise figure measurements in VHF conference proceedings.

However, all this is in support of developing low-noise VHF/UHF/
microwave amplifiers, and I see from further down your post that you're
actually interested in something quite different...

I'm sorry to hear that you are mainly confined to home, and essentially
to armchair theorizing (and that does explain something...)

The kinds will textbooks you find in Blackwell's (the huge Oxford
University bookstore, for the benefit of non-locals) are not really what
you need. What I'd suggest is a visit to www.agilent.com/find/nf where
you can download their Application Notes 57-1, 'Fundamentals of RF and
Microwave Noise Figure Measurement' and 57-2, 'Noise Figure Measurement
Accuracy'. These Application Notes are much closer to the interface
where theory meets practice, and they're free for the taking.

>
>> The reality is that for a few pounds or dollars, you can make a highly
>> effective noise diode source that will work from HF through to the low
>> microwave bands. And you can have it calibrated against commercial
>> sources at a "Microwave Round Table" Sunday for free.
>

>Just how stable is the calibration?

That's hard to assess, but after allowing for temperature changes it is
probably within +/- 0.1dB ENR long-term.

>Of what magnitude of noise temperature are you speaking?

Usually only about 600K or 6000K, which is all that's needed to measure
typical RF devices.

>Will any of the sources make 10^8ï¿½K?

No, and neither will normal measuring equipment.

>I want to be sure to bracket the temperatures of interest, an extrapolated
>result is probaly worthless beyond being an indicator.
>
Ah, I see what you want to do... For noise levels as high as that, the
best comparison source is a calibrated signal generator, using an RMS
detector at the output of a receiver.

Really the only reason for using noise as the test signal to measure
noise figure is that it's relatively easy to generate it at accurate low
levels. Signal generators are not used because of the problems of
attenuator and cable leakage which limit the minimum level of signal
that can be accurately generated.

On the other hand, if you want to measure a high noise level, all the
advantages and disadvantages reverse. It is not too difficult to
generate accurate high noise levels, but with a signal generator it is
very easy indeed so that is the best source. The RMS detector bridges
the gap between noise and a sine-wave signal, and away you go.

Another feature of high antenna noise levels is that they tend to be very variable, which means you don't have to worry too much about instrument accuracy.

If I understand you properly, you are saying that at a distance from a loop its field will be identifiable because the electric field will predominate, and at a distance from an dipole its field will be identifiable because the magnetic field will predominate.

Only problem is, it is NOT possible to tell by the ratio of electric to magnetic field in the far-field, whether the radiator was a magnetic loop or an electric dipole.

6049. Really ignorant question about antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-27 18:20:00 UTC
From: "Steve D. Perkins" <steve@NOSPAM.hotmail.com>
Message-ID: <99qlmf06o6@news2.newsguy.com>
Source record: 167324

I realize that this newsgroup probably caters more so to shortwave and CB equipment, but I have a simple question about plain ol' FM radio that I'm hoping people here will have the knowledge to answer.

At work I've been listening to streaming radio broadcasts over the internet on my PC. However, our network isn't the more reliable on earth, and I've discovered some excellant jazz
stations in the area that don't broadcast streaming internet audio... so I've brought in a small radio from home to listen the old fashioned way.

This is just a small AM/FM/CD-Player with headphones device, that uses the headphones themselves as the antenna. Reception is pretty crummy unless you sit just right (you know with
your right leg bent and your left arm held over your head!). I've gotten into the habit of plugging my headphones into the audio-out port instead, so that there is no external antenna
(and at least the signal will be CONSISTANTLY crummy).

This has given me the idea of plugging some real form of antenna into the headphones port to get better reception. Since most FM antenna seem to use an F-connector, I grabbed an F-connector-to-miniphone adapter from Radio Shack (and even that by itself gives a slight improvement). I don't mind grabbing a full-blown "rabbit ears" antenna to place on my desk, but it would be infinately more convienent to have a small telescoping rod antenna that I can
compact and store in my CD case with the player.

I've searched a few web sites, but haven't really found any that cater to radio equipment in great depth. Can anyone point me in the direction of some sites or catalogs where I can find a small telescoping rod antenna compatible with an f-connector or miniplug (or at least
confirm for me that no such creature exists)?

Sorry, even though I'm now a qualified member of the OFC, I don't recall what the Hula-Hoop antenna was. But the answer is probably no. The CTHA has a couple of toroidal windings, going in opposite directions from each other. The HF version does look like it's wound on a Hula Hoop, though, and the whole thing is covered with black electrical tape.

Hopefully I thought that it didn't show, :)
As for winning Reg I know that in the long run we all win some and looses some so I have no problem with owning up when I am convinced that I am wrong. I always feel that being wrong is an opportunity to learn, being right only confirms that I knew something all along and I have add little to my knowledge store. I would also guess that being right all of the time would indicate that I am well within the boundaries of human knowledge and that I am not trying to push the envelope. If I was not being wrong at least 50% of the time then I would feel that I was not where I wanted to be.

> You asked why I had never measured the efficiency of any of my
> antennas and got yourself caught on your own catch-question.

It wasn't a catch question Reg, I don't do those; I leave them for the clever Dicks that never did anything.
I am genuinely interested in the results of measuring the efficiency of your antennae and comparing those results with the other measurements that you have made concerning VSWR etc.

> Sorry I am unable to admit I don't know what the radiating
> efficiencies of my antennas are, because I DO know.

As they are subject to reciprocity they might be expected to have a similar efficiency on receive. as the measurement of sky temperature is in the first instance a fairly simple experimant, (disregarding very high precision initially). So you might have some idea of what the temperatures might be when viewed through yout AEs.

> But I havn't
> the foggiest idea of what the sky temperature might be at 1.9 MHz.

Fairy Snuff Reg.
On the basis that if you can't hear them you can't work them and the fact that at around these frequencies the limiting factor to signal to noise with low signal levels is the sky temperature and not the Receiver Noise figure a knowledge of sky temperatures is of great interest. For about a year when I could do little else because of my then invalidity Each listening session on HF I logged the sky temperature for the session. At that time I was monitoring RTTY and AMTOR as well as SSB (quite a lot on 20 but some on other bands.) By having some idea of sky temperature, but at that stage no idea of my AE efficiency I could calculate the Signal to noise of the incoming signals by counting the errors on the screen. Form this and a

knowledge of the S/N it is possible to infer a received signal level at the AE I/P. Although my experiments were crude and I have progressed them no further for the moment, other than being satisfied that the idea works and is capable of refinement. For the future the value for quickly assessing a new antenna and for some searching propagation measurements there is a lot of potential in the idea, especially if enough Hams take an interest and have a go for themselves.

Yes, I note from your comments below that most of the measurements are at VHF and above. As this conversation has the topic subject that it does I have been atempting to address the subject and trying to remain more or less on topic concerning 160 m

> There is lots of information on the web, for example in the 432MHz and

Yes thank you Ian, Hogg and Mumford et al. probably fit fairly well at these higher frequencies. It is the bottom of the curve that is of interest to me at the moment, does it flatten or plough on into infinity at f=0. :)

> However, all this is in support of developing low-noise VHF/UHF/
> microwave amplifiers, and I see from further down your post that you're
> actually interested in something quite different...

I was atempting, for once, to remain on topic.

> I'm sorry to hear that you are mainly confined to home, and essentially
> to armchair theorizing (and that does explain something...)

Yes thank you Ian. I was reluctant to mention my personal circumstance, but I felt that It was time to dispel any misunderstanding, so hopefully I will not bring up the subject again. Funny thing about mind experiments when you are not too well without the access to every now and then do some practical work, you can start chasing dragons fairly easily. However I think that so far in this thread I have tried to stick with what I know and have experience of and wher I have been over reaching that experience I have attempted to qualify my statements.

> The kinds will textbooks you find in Blackwell's (the huge Oxford
> University bookstore, for the benefit of non-locals) are not really what
> you need.

Pity They are just the stuff with which I am familiar. And I still feel more at home with a book than a screen for deep technical texts. Putting complex

equations on screen with only plain text can be frustrating. E. Brit for instance uses images of formula to overcome the limitation.

I will visit and download your recomendation thank you Ian. I can print the notes out and curl up in bed with them at my leisure.

That is pretty good for amateur work in the first instance.
If I could make all of my measurements with that sort of precision I'd be a happy chappie.

> >Of what magnitude of noise temperature are you speaking?

That is -80 dBm in 2.4 kHz bandwidth, (typical SSB pass band)

A good Rx should be able to cope with that level.
Especially if there is NO RF amplifier.

> >I want to be sure to bracket the temperatures of interest, an

> >
> Ah, I see what you want to do... For noise levels as high as that, the
> best comparison source is a calibrated signal generator, using an RMS
> detector at the output of a receiver.

Yes that is waht I want to avoid, the errors using a bolometer and an attenuator can accumulate. I have been that route before. What I am looking for is a primary standard that of it's nature requires no calibration. A LiN load and a Load at ambient with a thermometer on iot is fine for very low noise temperatures. I would like to duplicate the method but at very

high system temperatures, thus I look for some physical standard. What noise temperature for instance is a plasma?

> Really the only reason for using noise as the test signal to measure
> noise figure is that it's relatively easy to generate it at accurate low
> levels.

Agreed, what I would like is a very high temperature load that fits these same criteria. This would make it available easily to any Ham sufficiently interested to want one and learn how to use it. Once again with a good physical standard high noise source an attenuator soon makes such a load quite useful as a calibration standard.

>Signal generators are not used because of the problems of
> attenuator and cable leakage which limit the minimum level of signal
> that can be accurately generated.

Yes I am familiar with the problem when attempting to plot threshold on an AGC curve. I think the answer is a small device powered by its own internal batteries and completly sealed and no power leads to it. The device would plug directly into the I/P AE terminal/connector of the receiver under test.

> On the other hand, if you want to measure a high noise level, all the
> advantages and disadvantages reverse. It is not too difficult to
> generate accurate high noise levels, but with a signal generator it is
> very easy indeed so that is the best source.

For some testing a noise souce is better, a coherent source requires accurate tuning to the right point on the pass band curve tyo ensure that you are using G(Fs) that the receiver will use in practice. A noise source completely avoids this problem and also it operates upon the Equivalent Noise Bandwidth of the filter ae noise does in pratice. Also no correction factors for the type of detector need not be applied when making noise measurement.

>The RMS detector bridges
> the gap between noise and a sine-wave signal, and away you go.

Yes that is a whole new topic, I spent some months comparing the various possible detectors and their form factors. If any work that I do is to be of use to the Ham fraternity in general such calibrations should be avoided wherever possible by using noise.

> Another feature of high antenna noise levels is that they tend to be
> very variable, which means you don't have to worry too much about
> instrument accuracy.

Whe you say variable there are periods when the rate of change is small and the measurements can be made to reasonable precision by measuring in the gaps between the dots and dashes of a fairly slow morse transmission some fairly good comparisons can be made on an integrating meter of noise from a resistor at ambient temperature and the noise from the antenna that originates in the sky.

A step attenuator with about 80 dB or more total attenuation and a least step of 1 dB can act both as the Ambient load and the attenuator for measuring the noise delivered from the Antenna.
The home made step attenuator described in the ARRL Hannd book is quite suitable if fabricated from double sided PCB and all is soldered with compartments for each section of attenuator. The one which I constructed is a binary series as this produces every step of attenuation in 1 dB steps at the lowest cost and the most convenient resistor values. Mine actually does 71 dB and I add an external pad or use the Attenuator built into the Rx having first calibrated it.
The steps that I have are 20, 20, 16, 8, 4, 2, 1 dB
These have proved Ok to use to measure sky temperatures to within 1 dB

The integrating meter is of my own design and it doubles up to crudely indicate S/N when receiving SSB It plugs into the record O/P of the Rx. It is an active device. The time constant is switchable.
I *will* calibrate my antenna efficiency over the spectrum of interest one day.
At the moment I think it is something like this:

1.75 MHz -|- ?
3.5 MHz -|- 17%
7 MHz -|- 53%
10 MHz -|- 17%
14 MHz -|- 84%
18 MHz -|- 44%
21 MHz -|- 15%
24 MHz -|- 2.5%
28 MHz -|- 27%
29 MHz -|- 23%

Cecil, no problem ! Use program ENDFEED (or several others) to find antenna height to produce the following input resistances.

Height of Vertical Radiator in Wavelengths	Input Resistance Ohms	Input Reactance Ohms	Tune Capacitance Picofards
0.250	37	0	-
0.269	50	- 38	140
0.292	75	- 84	63
0.322	100	- 151	35

With a group of elevated horizontal radials, each 1/4-wavelength.

Shallow-buried radials in good ground can be any length.

Above reactances and capacitances apply at 30MHz. Antenna rod = 0.4" diameter.

If elevated radials are less than 1/4-wave then the input reactance can be made zero. But current will flow on outside of coax.

Regards, Reg, G4FGQ

You might head back to Radio Shack and ask to see their 2001 product catalog. On page 166 is a selection of FM antennas -- from a $2.99 wire dipole to a number of snazzy-looking amplified antennas. On page 167 are some TV set-top, rabbit ear style antennas, some of which include FM reception, too.

I'd start with the little wire dipole. It'll probably work as well as any of the other, more expensive stuff.

Even in the near field, you are unlikely to know. The exception would
be within maybe 1/10th of a wavelength or less.

Roy explained the field behavior pretty well, but I guess it fell on
deaf ears. That may be a requirement to keep thinking the shield has
some meaning purpose other than balance.

Bart agreed, Bill agreed, Roy agreed, Reg agreed, Reference Data for
Radio Engineers in the later copies agrees. Faraday and Maxwell agree.
The only people who disagree are those who use the examples of
transformers out of context for evidence.

I think everyone else has given up, and so will I. Some things are
hopeless, and not worth the time.

Steve- I know some of the answers have been slightly facetious, but- the obvious cure is to get a better radio, one that has a connection for an antenna. Try this, then , if the reception is still bad, try an added antenna.
You have not told us much about the physical set-up at work. The type of building structure, how far you are from "outside" walls, whether you can get access to outside for an antenna, etc, are all things that will help people help. So far, the question is almost "how high is up", and no one can answer.

Give us the real info, and you may get better answers.

Good luck-Bill-W4BSG

> solid core? Wrap them with padding?

They are wound on lightweight plastic cores about 2-.5-3 inches dia. I put plugs in the ends and drill holes to mount on the sticks I use. The wire is #12 house wire with the insulation on, and then I wrap vinyl over the coil when I'm done to waterproof. And yep, I'm sure your thinking all this stuff will ruin the coil, but in practice it doesn't seem to. I've compared with equal size bug coil antennas, and could see little if any difference with the plastic core and vinyl. You can hit a tree and doesn't faze one of these. There is nothing to break. I guess you could make one with all the right connectors. You might try
just taking a piece of wire and wrapping a whole lot of turns around the
headphone wire near the player, and then running the wire off to a place
that seems to get the station. You might get it to work just from the
capacitive couplng of the extra wire to the phone lines. But , if the
phones line is shielded, this might not work. You might want to consider
a better radio with a real antenna connection. IE: stereo receiver etc.

You can usually do it without a cap is the radiator is long enough.
Within limits anyway. "1/4 wl design". MK

6071. Corrections for previous data.

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-28 00:59:30 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <99rd07$a79$1@neptunium.btinternet.com>
Source record: 167344

Cec, please disregard the previous figures which were produced in haste and very inaccurate. I had pushed the program beyond its validity limits. On reflection, the figures didn't look right. The following data has been produced using program VARNEY to compute input impedance of a dipole and dividing by two.

Input Impedance versus Height -

Height of Vertical Radiator in Wavelengths	Input Resistance Ohms	Input Reactance Ohms	Tune Capacitance Picofards
0.250	37	0	-
0.288	50	100	53
0.328	75	222	24
0.352	100	303	18

With a set of elevated horizontal radials, each 1/4-wavelength.

Shallow-buried radials in good ground can be of any resonable length.

Above reactances and capacitances apply at 30MHz. Antenna rod = 0.4" diameter.

If elevated radials are less than 1/4-wave, (height + radial = 1/2-wave) then the input reactance
will be zero, but the coax will radiate and some people don't like that.

Regards, Reg, G4FGQ

6072. Coil Form Material

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-28 01:03:21 UTC
From: "David L. Dyke" <dld@NOSPAMrglobal.net>
Message-ID: <99rd8k017g1@enews4.newsguy.com>
Source record: 167346

I am wondering about the 'have to' vs the 'ideal' coil form material. I realize that an air or glass coil form is about ideal (constructing a high-Q coil), but what if all I can obtain is plain-old white PVC? How much of a loss of efficiency can I expect at RF frequencies?

Simple question, I know, but I am looking for opinions. (B & W coil stock is outrageously priced, plexi-glas is noot cheap either, and I do not have a source for fiberglass tubing.)

Thanks in advance.

Tom, W8JI wrote:
"My point is you have to be VERY careful how you use radiation resistance."

Terman defines radiation resistance as:
"This is the resistance that, when inserted in series with the antenna, will consume the same amount of power as is actually radiated. The magnitude of the radiation resistance depends upon the antenna configuration and upon the point in the antenna system at which the resistance is considered as being inserted (clearly, radiation resistance is an analytical tool). Unless specifically stated to the contrary, it is customary to refer the radiation resistance to a current maximum in the case of an ungrounded antenna (like a balanced dipole), and to the current at the base of the antenna when the antenna is grounded (or operated against ground like a vertical resting on a base insulator)."

It is well to define what you mean by radiation resistance. If you don`t say what you mean, most informed recipients of your message are likely to think you are using the Terman definitions.

Is that because the current into the vertical radiator and the
current into the radials are not equal?

Steve,
I've had my G5RV up for a year now and think it works great. I have it mounted 75' high. If you can use insulated wire it will protect the elements from oxidation. It gets a little gain on 20 and 15 meters, and on 40 and 80 meters it approximates the gain of a dipole.

I have the full sixed version (102') and use it with an antenna tuner. Good luck and 73.

I'm sorry, but you're not getting my thermonuclear device until you pry it from my cold deap fingers (not to mention a few hundred thousand other cold dead fingers).

Anyway, lets not be silly - the two examples just don't fit together. Private ownership of firearms is a tradition that goes all the way back to the very start of this country (every person who signed that Constitution, and the Bill of Rights, owned a gun), but I'm not aware of anybody who is honestly suggesting a right to privately own a thermonuclear device, nor is there any tradition of such ownership. In other words, these two are not even in the same ballbark - in either capabilities or political debate.

6081. Misleading Statement in Antenna Book

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-28 03:25:30 UTC
From: mover123@webtv.net
Message-ID: <3238-3AC159AA-224@storefull-245.iap.bryant.webtv.net>
Source record: 167354

I own the 15th edition of the Antenna Book (1988). Chapter 2, "Antenna Fundamentals" includes the following statement in the third paragraph: "Other factors being equal, field strength is directly proportional to current. It is therefore desirable to make the current as large as possible for a given amount of transmitter power..."

This statement seems to imply the supplied power is not what determines the strength of the radiated field. There is clearly something misleading about this statement as it stands. Perhaps if they used "available power" instead of just "power", it would make more sense. I think I know what was meant, but it is unfortunate that such statements exist in the basic literature that newcomers are exposed to. Comments welcome.

Thanks, Paul

Tom, W8JI wrote:
"The difference between a single reflector and multiple reflectors (trigonal) is nearly immeasurable."

Tom may be right. Support for his opinion would be interesting.

A reflector element is usually placed about 1/4-wavelength from the radiator. This is for the desired phasing, and the reflector length can be altered and the spacing can be changed with the same phasing result. I am using 1/4 wavelegth to simplify the following explanation.

The reflector is about 1/2-wavelength long and has low resistance. It is parallel with the radiator element. Because it is near resonance, the reflector readily accepts energy from the radiator. Because it has no load or significant loss resistance, it must re-radiate the energy it accepts.

By Lenz`s law we know the induced field must oppose its creator. We also know that if the conductor is nearly lossless, the re-radiated energy and energy direct from the radiator will balance to nearly zero in the direction of the reflector.

But the reflected energy returning towards the radiator has gone through 90 degrees to get to the reflector. At the reflector it underwent another 180 degrees. On the return to the radiator it undergoes another 90 degrees of phase change. The total phase change during the roundtrip from radiator to reflector and back to the radiator is 360 degrees. This phase rotation puts the reflected energy in phase with the energy newly emerging from the radiator. We have a power gain in the forward direction.

In the trigonal reflector, only the middle reflecting element shares a plane with both the radiator and the directors in the parasitic array. Energy directed towards the upper and lower reflecting is in a different plane from that directed at the middle reflecting element and can evoke its own responses.

I have no experience with the trigonal reflector. In my experience, all of the arrays I`ve used that had multiple reflectors had multiple radiating elements, one for each reflector. But I can`t say the trigonal reflector won`t work, either. I can only observe that people have built them and probably thought they were worth the effort, or they probably would have not got them published in several respected places. I did not recommend the trigonal reflector. I only had a source of design details which I gladly supplied.

Best regards, Richard Harrison, KB5WZI

First thought: The balun may be bad. Or it may be introducing unwanted
reactance at the feedpoint. It can measure OK with a VOM and still be no good
at 28 MHz. (All it takes is one shorted turn). You have checked so many other
things that it's the next thing I would check.

Try making up the dipole without the balun. Try 8 feet 3 inches on each side, measured from the coax connection point to the eye of the end insulator.

How high up are you mounting this dipole? Height above ground makes a big difference in the feedpoint impedance.

I'm not sure I follow you... What might those "ARRL's singular interests" be and what do you propose as an alternative to the *only* national amateur radio organization? Cutting off one's own nose to spite the face is usually not a smart choice.

Look, clearly it is in every US ham's interest to retain as much spectrum as possible for as long as possible. Fiber optics in every house will alleviate the pressure, but it will not eliminate it. Everything else is petty stuff which is not critical for the survival of amateur radio. Once we absolve this fact, the choice is simple: we either support our one and only ham radio representation in the world or not - we keep our hobby alive or not.

Well, geez, every person who signed that Constitution was also a slave owner,
but you could hardly condone that nowadays, especially with all these nutcases
running around demanding their $1 million retribution in gold bars.

> , but I'm not aware of anybody who is
> honestly suggesting a right to privately own a thermonuclear device, nor is
> there any tradition of such ownership. In other words, these two are not
> even in the same ballbark - in either capabilities or political debate.

Why not? I am simply asking for consistency: a thermonuclear device falls into
the same category of "firearms" as a six-gun. They are both devices used for one
purpose only: to kill people. Everything else is a smokescreen. Now, it would
seem to me that the very same amendment you guys are pulling in the case of
handguns, rifles and automatic weaponry must cover *all* firearms. One person's
definition of danger is another person's definition of safety. What this boils
down to is this: that amendment is somewhat anachronistic.
Btw, neither you nor Dick commented on the second part of my example - the
narcotics use. But I admit, here we are dealing with one of those things that
make people feel good and politicians re-elected. War on drugs. Any day now.

73 ..... Zoran WA7AA

And in case anyone's wondering: I own neither a handgun nor a TND, but I do
support a right to bear a handgun or two; I also support legalization of all

drugs except to minors, followed by revamping of the legal system with the emphasis on expanding a death penalty. Too radical? Hell yeah, but with 1% of the US population in prison, something better be done before it gets worse.

I wouldn't call the ARRL the "sole" protector of amateur radio in the U.S.
Many amateurs, whether as individuals or as groups (clubs, repeater
coordinators, or others) comment on pending FCC rulemakings and write
Congress-critters (as they are called in another newsgroup). Only if the ARRL
were the only entity talking to the government would the title of "sole
protector" be appropriate. Nothing says that each individual licensee can't
comment directly and must go through the ARRL.....

Nothing says that - you're right. However, how much clout do you think US hams would have with FCC and congressmen if they kept showing up in groups of 5 to 10, without unified representation, on a strictly individual basis? We could all comment ourselves right out of all the spectrum.

Nothing says each individual US citizen can't fight an invading army on his own and in groups, but doing that would be the biggest mass suicide since Jim Jones. That's why we have the US Army. And that is also why we have the ARRL - to have a strong, unified and committed representation so we don't look like a bunch of jokers. Frankly, I don't understand what's all this dislike of the ARRL - what's the big grudge? Would someone care to explain?

Walter... we agree. I am with you on this issue. But the IEEE's Chief Lexicographer has already done his damage. Oh well.

BTW... do what do you think of the concept of imaginary resistance? jR is not only a concept but it is "real". Imaginary resistance is quite useful for explaining the operation of "narrow band" antenna tuners and certain other impedance transformation effects in both broadband and narrowband contexts. It is sometimes useful at intermediate steps in the synthesis of broadband matching networks.

Imaginary resistance is quite useful as an analysis tool, and...

In fact, with some expense, imaginary resistance can be "approximated" in the lab to as much precision as is desired (Over a prescribed finite frequency band).

Here is a question for the NG... given that imaginary resistance can be "approximated" as closely as desired, is there any practical use for it?

Best regards,

-Peter K1PO

Come on now, even Clinton couldn't make that one fly.... A gun can only
kill a single person within the shooters' direct line of sight per
discharge. This weapon targets a specific person, and has the option to
only wound, as well as kill. It does not destroy the surrounding buildings,
all life forms in the surrounding area, and pollute the land with radiation
for the next several centuries.

If what you say were true, then the ATF would be enforcing the laws
regarding Nukes... :>)

"David L. Dyke" <dld@NOSPAMrglobal.net> wrote in message
news:99rd8k017g1@enews4.newsguy.com...
I am wondering about the 'have to' vs the 'ideal' coil form material. I realize that an air or glass coil form is about ideal (constructing a high-Q coil), but what if all I can obtain is plain-old white PVC? How much of a loss of efficiency can I expect at RF frequencies?

Simple question, I know, but I am looking for opinions. (B & W coil stock is outrageously priced, plexi-glas is noot cheap either, and I do not have a source for fiberglass tubing.)

Thanks in advance.

73 de N6XOS (Dave) dld@rglobal.net

Dave: I've turned to toilet paper tubes (sans paper), Brawny paper towel tubes (sans paper), and, most recently, the Quaker Oats cylinders (sans oats).

For any of them (chosen for their diameter and length, depending on my "L" and "Q" needs) I cut up a couple of 1/8" wooden dowels to the same length as the tube and epoxy the dowel pieces laterally along the form - that way I get the wire elevated off the form enough to employ alligator clips or, in one case, solder wire tap points to connect to a multi-ganged switch.

Works for me - expect the cardboard form to have little effect on the Q of those coils.

Regards, Jim R. K9JWV

Dear Elmer:

I am considering a permanent antenna mount for 2m/70cm. I am seriously considering a NMO in the center of the roof of my vehicle vs. any other type mount.

It is suspect that there would be a HUGE increase in performance with this type of installation.

I am kind of "on the fence" with this decision.

My concerns:
1.) parking garage issues
2.) resale or trade-in of the vehicle
3.) leaks ...rain or water issues???

I am guessing there are many HAMs out there that have considered this and decided one way or the other for various reasons. I would love to hear your arguments in either direction.

Thanks in advance,

<snip> Taking a lesson from an off-center fed dipole, if we make the horizontal radials shorter than 1/4WL and the vertical radiator longer than 1/4WL, can we find a 50+jX ohm point? (where the reactance can be neutralized with a series cap) I've been meaning to model that configuration but day-trading has soaked up my time.

Mark replied:

You can usually do it without a cap is the radiator is long enough. Within limits anyway. "1/4 wl design". MK

Mark and Cecil: I'll be trying this approach out (shortened radials and a tunable vertical radiator) over the coming week. I'm planning on activating a new U.S. Island that's out in the boonies so I'll need to use a boat to get to the bloody place - consequently, need to keep the antenna system lean and mean. Plan on working out a vertical antenna arrangement that leverages off Cecil's modified ham stick creation for 20 - 10. Will be stabilizing the vertical off the boat's edge and deploying a shortened radial system; e.g., 30 to 40 radials of a length around 8 to 10 feet. Hope to leverage off the fact I'll have the base of the vertical at the water's edge and can deploy most of the radials in the salt water. I can construct and install the system at my home as I live at waters edge so I'll use an Autek Research Model VA1 analyzer as I'm atunin' and adjustin' - so, I'll get the impedance, R and X components, L and C readouts. Outta be interesting. If you're interested I'll be glad to report back on what happens. Regards, Jim R.

CC wants something like $80.00 for their "match box" for my X7 beam that I don't even know is bad yet but I need to have one on hand for the tower guys when they come to help. I think it is unlikely that traps went bad. CC wants about $35.00 to $40.00 each for those as well. I could always use the balun on something else if the XM79 box is still good.

Who makes a good 2kw 4:1 balun?

What is the best way to test a balun (on the tower)?

Just another thought. As Jim says, a VOM is not a good way to check a
balun.
You can't really tell how it is going to work at various RF frequencies.
However, you did say that you had a MFJ antenna analyzer. If I remember
correctly, in the instruction manual there are instructions on properly
testing a balun using the analyzer and a couple of resistors. I have
done
it before, but I don't remember the procedure off hand.

You are just as wrong as you can possibly be, as most anti gun people consistantly are. I have absolutely no intention of killing anyone with a gun, but I also have no intention of allowing you to confiscate them. I DO have an intent to use them - the mere existance and presence - to deflect those who would cause bodily harm to me and my family. Almost always, the mere sight a weapomn of defense is more than enough to put the coward to flight. Should the assailant be in an unusual state of mind, such as drugged or insane, and insist on forcing me to use a firearm to stop him, of course that would be the natural progression of things.
Soit was when columnist Mr. Carl Rowan, a rabid anti-gunner, shot an intruder. He sure changed his tune in a hurry. Curious thing, that he even OWNED a gun, what with all his anti-gun rhetoric, isn't it? Do YOU own gun, by the way?

Now, it would

As to issue #2(resale value), here's an idea.

I have a friend that recently sold his vehicle that had been drilled for NMO mount(on the roof). When he was ready to sell, he simply swapped out the 2-meter antenna with a cell phone NMO antenna. He explained it as a "feature" instead of a "problem". The guy who bought it "didn't know you could do that" and "didn't realize his cell phone could work so well". A simple 5 minute demonstration, and the buyer was okay with the "problem".

When you have lemons, find a way to make lemonade.

The one or two times a year I deal with this, I just unscrew
the antenna when entering.
>2.) resale or trade-in of the vehicle
I drive them 'till they drop so this is no problem to me
>3.) leaks ...rain or water issues???
Never had a problem with my NMO and Larsen antenna

If you have an SUV, where no one will see the plug when you trade
vehicles, drill the hole. If you have a regular height car and plan
to trade, I'd use some kind of trunk lid mount.

OTR

PS
You do know that there is a special drill bit made to do this? I'd
hate to see your drill bit grab and poke through your head liner.

I would (and did) go with a SO-238 UHF style mount. It's compatible with more antennas, and the hole in the roof is smaller. It's easy to fit a small hole plug if you remove the antenna, and a dab of touchup paint and it is barely noticeable...

Another neat feature - if your into camping or field day, you can remove the antenna and connect a run of coax to the mount to allow the use of a small yagi in a tree or on a push up mast...

(And your correct concerning the performance improvement over a typical window or gutter mount.)

Hi John:

I don't know if you will see a huge increase in performance with a permanent mount but you will see some. You will see the most if your replacing a through glass antenna. If you are replacing a magnet mount, the biggest change will be in stoping the slow deterioration you will see when the coax is smashed in the door over and over.
As for resale value on the car, before I did it to my pickup, I asked a few people I knew in the used car business. They told me that it had no real effect on the value after the car was a year old. So unless your trading cars every year no problem.
As for leaks, I've never had any problems, but I went to a local 2 way radio shop and had them put it in. It didn't cost much and they did it right. I use a 2m/70cm antenna that is a loaded 1/4 on 2m and a gain antenna on 70cm. It's slightly shorter than a standard 1/4 wave. Here in Pennsylvania the advantages of higher gain antennas is not so clear as the lower angle of radiation is not so useful in the mountains. It works just fine and I have no problems with my garage or parking ramps with my S10 pickup.

First and formost, selfpreserveation, on a the BOD level. Consider the
January vote on whether or not to support code testing at the next ITU
meeting.
The vote to drop code testing was by a voice vote, with no identity of
who voted how. There was a lone effort by a BOD Member to poll the BOD
for each member's vote, which was quickly voted down. None of those
voting against keeping code testing wanted his vote made public, and
without a individual poll of the vote it will not be, officially at
least. Since the BOD members are elected as individuals, the entire BOD
can't be held accountable for such a vote since they can't be elected
nor unseated en masse.
Just a bit of defense against the will of a large bloc of ARRL
members' wishes. Selfpreservation at it's finest.

and what
> do you propose as an alternative to the *only* national amateur radio organization?
> Cutting off one's own nose to spite the face is usually not a smart choice.

Oh, no, alternatives haven't proved viable to date. Just understand that
the enemy is not always outside looking in.

>
> Look, clearly it is in every US ham's interest to retain as much spectrum as possible

> for as long as possible.

Not at all. We use little of our UHF/SHF allocations, and it might very
well be in our best interests to "trade" some of that unused real estate
for some we could make better use of, maybe on HF or VHF. I think that
most of the Part 15 intentional radiator devices would be much better
off above UHF instead of on HF where they do far more damage, but that
battle was lost long ago.

Fiber optics in every house will alleviate the pressure, but
> it will not eliminate it. Everything else is petty stuff which is not critical for
> the survival of amateur radio. Once we absolve this fact, the choice is simple: we
> either support our one and only ham radio representation in the world or not - we

And while we're at it, keep the heat and pressure on them...

Tom, W8JI wrote:
"I think everyone else has given up, and so will I."

Tom should give up because he is dead wrong.

The shield on a loop antenna is a Faraday shield. Faraday shields are sieves which pass the magnetic field but don`t pass the electric field.

Origin of the fields affects the % of each field arriving at the sieve, but doesn`t affect the electric field blocking of the sieve. When there is a disproportionate electric field as the result of noise nearby, the Faraday shield has an opportunity to sieve out some of the noise.

The issue that Tom has been adamant on was:
"The electric and magnetic fields are INSEPARABLE."

I am just as adamant that he is dead wrong on inseparability.

The Faraday shield does this job in many locations including loop antennas. Tom has not given any explanation to support his claim of inseparability. I have explained how the Faraday shield works.

The Faraday shield is used in millions of 50/60 Hz transformers to sieve out higher frequencies which might be detrimental. The Faraday shield is also used at r-f in every mediumwave broadcast transmitter I ever worked with, and that is a bunch, for exactly the same purpose. It is used to eliminate capacitive coupling. Capacitive coupling favors higher frequencies. So, the faraday shield intervenes between transmitter and antenna to kill the capacitive coupling so that harmonics won`t get a leg up.

Come on Tom, throw in the towel. Don`t try to declare victory and fade away.

Best regards, Richard Harrison, KB5WZI

Because slave ownership is illegal nowadays while gun ownership is still
protected by the 2nd Amendment.

> ... a thermonuclear device falls into
> the same category of "firearms" as a six-gun. They are both devices used for one
> purpose only: to kill people.

Actually, pistols are most often used as a deterrent to avoid killing
people. All I had to do one night was to display my 9mm and the mugger
with the knife broke an Olympic record running away.

Did you hear about the eight year old who got suspended for pointing a
chicken strip at a teacher and saying "pow"? One wonders what would have
happened if he had pointed the chicken strip at a teacher and said, "yum".

> Give us the real info, and you may get better answers.

There's really not a whole lot to say... I'm not needed a truly nice high-quality setup, just a little portable solution capable of fitting in the pouch on my CD carrying case that will give me decent reception for FM stations within the city limits (10-15 mile radius max).

My office is in the middle of uptown Atlanta, I'm on the 17th floor, nearest window is about 15-20 ft. away (ability to mount an outdoor antenna is out of the question, and would be
overkill for my needs in any case). The radio is nothing special, a little Chinese radio/CD-player gadget that fits convienently in a pouch inside my CD carrying case. It has a
headphones jack (that doubles as the antenna), a miniplug line-out jack, and an AC adapter plug
that makes it nice to use at home, work, or the car (using a cassette adapter).

I believe that I found a possible solution. After tinkering around some more on the internet I found some more suppliers of RF components... so I ordered a small telescoping antenna with a BNC connector, and an adapter to go from BNC to F (for the F-connector to miniplug adapter I already have). I'll either plug my small antenna contraption into the headphones jack and keep my headphones in the line-out plug, or maybe use a splitter to plug
both into the headphones jack (as I said, I can't control the volume when plugged into the line-out jack).

Another small question someone may know. Like I said, this little radio uses the headphones plugged into it as its external antenna. Plugging an F-connector-to-miniplug adapter into the headphones jack doesn't seem to hurt anything, but is there any chance that
plugging a real antenna (or anything that acts as a terminator) into that jack could damage the
equipment or give the antenna a dangerous electrical charge?

6113. Re: Coil Form Material

Newsgroup: rec.radio.amateur.antenna

Message-ID: <3ac20415_2@news3.prserv.net>
Source record: 167286

Interestingly enough, the 'loss' due to PVC is not from loss tangent, but rather from increased capacitance between turns of the winding. The design of coils for higher dielectric constant core material differs from air core. To approximate air core design, space the wire away from the tube with radial spines, made as narrow and tall as practical. Having the wire tight against the PVC is what does the 'damage'. Or use flat stock in an X configuration. The old coil designs, before machine windings, and development of specialized materials was based on experimental determination of what works best. Another alternative is Styrofoam cylinders from craft and hobby shops. It has practically no loss at all, being mostly air. It does take a little care in winding, as it crushes, but when slightly mashed, holds the turns in place.

Howdy,
I used to always drill and mount in the top. Lately tho I've been using mag mounts. They are mechanically sufficient for 2m/.7m ants. And also do a good job electrically

A true story: Many years ago I had a rather husky 6-m whip on a spring base on the side of a VW microbus.

Whilst driving thru a multi-level parking garage in Indianapolis, I began to hear a crashing noise. They had a 4-ft fluorescent tube mounted on each of the concrete "joists" which were separated by about twenty feet. I figured I took out about 15 or so of those lights. Needless to say I changed my mind about parking there and headed for the closest exit.

I returned to that same garage a month or so later to find that they had installed wire guards around all the lights.

However you mount the antenna, the top oh the vehicle is clearly the best location.

For harmonically varying E and H fields in a non-conductor, an E field begets an H field and an H field in turn begets an E field. The curl properties of E and H fields assure this.

If a material of some kind allows only an H field to pass, when the H field reaches the other side of the material and leaves it and re-enters a non-conductiong region, it will then resume the creation of the E field, just as it did before reaching the material.

The electromagnetic wave then continues on from there. Guaranteed.

What the value of Z0 (E / H), is on each side of the conducting material depends on what factors may be influencing the wave on each side of the material.

There is no such thing as a transformer of any kind, conventional or transmission line, that does not involve both E fields and H fields.

Source record: 167292

James,
That's sort of a loaded question (pun intended). It depends
on a number of things, how bad is the mis-match, do you ever plan
to use more than 100-200 watts, how much is too much($$). It never
really hurts to have 'too much' tuner. Especially with MFJ, always
select a tuner that handles at least twice your power output (3x is
better). If your open to used tuners, there are a bunch that would
work well for you. I have a Dentron MT-3000 that's never given me
any problems (not for sale). So, shop around, compare prices, go for
a tuner larger than what you need. Good luck...
'Doc

PS - You might consider building one, not really that hard to do.

Paul:

Because I don't see anything misleading about the quote from the ARRL Antenna Book, I have had some difficulty understanding what you think is wrong with it.

Of course, you are correct in stating that the power supplied to antenna affects the current flow and therefore the field strength. But that would be a scenario where the antenna is the constant and the available/supplied power is the dependent variable. That is not the scenario the Antenna Book is talking about.

The writer of the part you quoted was talking about transmitter power being constant and the antenna (or changes made to it) being the variable. My reading of "Other factors being equal" and "a given amount of transmitter power" means that there are no changes in power to affect the antenna current when you make your field strength comparisons.

What am I missing?

The nice thing about a reflector is phasing is correct for ANY spacing much less than 1/2 wl.

>The reflector is about 1/2-wavelength long and has low resistance. It is >parallel with the radiator element. Because it is near resonance, the >reflector readily accepts energy from the radiator.

The optimum reflector is at resonance when at modest spacings.

>from radiator to reflector and back to the radiator is 360 degrees. This >phase rotation puts the reflected energy in phase with the energy newly >emerging from the radiator. We have a power gain in the forward >direction.

The signal in the forward direction does not need to be in phase to provide gain. It simply has to be less out-of-phase than in the other directions.

Many antennas work on this principle.

>reflector won`t work, either. I can only observe that people have built >them and probably thought they were worth the effort, or they probably >would have not got them published in several respected places. I did not >recommend the trigonal reflector.

Trigoinal reflector have a fallen by the wayside as measurements and models have proven them only margially effective. They never lived up to the supposed advantages.

As was pointed out by others, you never see them now for good reason.

Not stubs, series section transformers in a 1,2,4,8,16 ft arrangement.
Throwing the knife switches is lots easier than twisting three analog
knobs.

Ah yes. A flashback to my youth. When I got out of high school, I
bought a 1937 Chevrolet coupe and installed my 10-meter rig in it.
Used a full-size 1/4 wave antenna. I pulled into a 76 station for gas
and took out every fluorescent lamp in that bay. Sounded like a war.
Unfortunately, this was also the station I worked at on weekends.
Needless to say my boss was not a happy camper. :-)

I have a pair of KLM amateur radio satellite antennas for sale. Both antennas are in good condition and each has the optional polarity switcher. Because these antennas are already assembled I can not ship them. I am willing to meet someone halfway up to about 100 miles or so. I am located in Union County, NJ.

I will sell both antennas for $150.00 or any reasonable offer. I want to sell the pair together.

You can view the antennas at the following URLs:
http://headhamster.homestead.com/files/ForSale/KLM_VHF.jpg
http://headhamster.homestead.com/files/ForSale/KLM_UHF.jpg
Please take a look!!!

Why? What if your "radiator of opportunity" is another loop? Must not reciprocity apply and the noise source be a "magnetic radiator" (near field of course)?

Bill Sabin wrote:
"There is no such thing as a transformer of any kind, conventional or transmission line, that does not involve both E and H fields."

I certainly agree. I have never posted to the contrary. The E field on one side of the Faraday shield is blocked. The E field on the other side of the shield is re-created from the H field that the Faraday shield let pass through. I already said this in previous posts.

Cortland,

I wanted to make a few comments and I couldn't quite figure out which message to follow up. I chose yours, but I think that you and Tom both agree that you can, in principle, separately measure the electric and magnetic fields.

Generally what is a magnetic induction B and what is an electric field E is determined (and defined for that matter) by the force on an electric charge q, F = q (E + v x B), where E and B are evaluated at the position of the charge. You then in principle measure the fields separately by measuring the part of the force that is independent of velocity, and the part that is dependent on the velocity.

Since the charges in copper have a relatively tiny magnetic moment compared to their charge, the force on them is well described by this equation. The average velocity of the charges in a small region of the copper is zero with no field applied. Therefore, if you somehow only applied a magnetic field, no current would flow, since the net force on the charges is zero. As many have been saying here, Maxwell's equations tell you that a changing magnetic field in a finite region gives some electric field in that region too. There just isn't any way around this if you accept Faraday's law, since it says that the average electric field along any closed loop is proportional to the changing magnetic induction averaged over the area through the loop. The only way to have the electric field zero everywhere is to have zero oscillating magnetic induction everywhere.

Notice that Faraday's law does not contain any material properties, so this is equally true in copper and in vacuum.

In a small loop antenna (or a transformer winding for that matter) the charges are being pushed primarily by that electric field. The fact that it is easier to calculate the electric field component that contributes by using the magnetic field is why this is called magnetic coupling. However the fact remains that it is the electric field that is doing the work.

When you think about how the magnetic field is used in calculations, it is obvious that a loop antenna is not really responding to the magnetic field. When the loop response is calculated from the magnetic field, it is the magnetic field through the area surrounded by the loop that is used. There is no copper there and therefore no copper electrons. Instead, this changing magnetic field must be accompanied by an average electric field around the perimeter of the loop. It is this electric field that pushes the electrons around the loop. That is, charges are pushed by the fields at their position. They are not pushed by fields somewhere else. That we can calculate the field that is doing the work by calculating the fields somewhere else does not change this fact.

Roger Leon, K6XQ wrote:
"I have some difficulty understanding what you think is wrong with it."
(An ARRL Antenna Book quotation)

Actually there is nothing "wrong" if the whole paragraph is quoted.

I thought Paul was complaining that the text said "---make the current
as large as possible for a given amount of transmitter power."

That might have seemed ARRL was recommending low impedance antennas. It
turns out that later in the paragraph:
"---the largest current will flow when the reactance is "tuned out"---."
appears and explains the earlier sentence.

Seems to me the author wanted not to say you need a "conjugate match" to
maximize power to the antenna. Help! Walter! We need that new edition of
"Reflections" PDQ.

Source record: 167310

Sorry for the additional posting, but I'm still struggling to figure out how to calculate and apply this new-found (to me) quantity of "dissipationless resistance". I know how to calculate resistance, but need some more help with the "dissipationless" kind. Any characteristic that can't be expressed numerically is of limited engineering use, so I'm sure "dissipationless" resistance can be easily calculated. But I need some help -- perhaps some of you more experienced folks could help me out. I've calculated the impedances of the following items, and the resistance is of course just the real part. But how much of each is "dissipative" and how much "dissipationless"?

Impedance of free space, 377 ohms.
Disspative resistance, ohms ______
Dissipationless resistance, ohms ______

Impedance of average soil at 10 MHz, 30 + j26 ohms.
Disspative resistance, ohms ______
Dissipationless resistance, ohms ______

Impedance of lossless cable, 50 + j0 ohms.
Disspative resistance, ohms ______
Dissipationless resistance, ohms ______

Impedance of RG-58 at 150 MHz (6 dB/100 ft loss), 50 - j0.24 ohms.
Disspative resistance, ohms ______
Dissipationless resistance, ohms ______

Impedance of RG-58 at 1 MHz (0.32 dB/100 ft loss), 50 - j1.9 ohms
Disspative resistance, ohms ______
Dissipationless resistance, ohms ______

Transimpedance of National LM359 amplifier 314,000 ohms
Disspative resistance, ohms ______
Dissipationless resistance, ohms ______

I assume the models can have "dissipative" and "dissipationless" resistances in series for mathematical convenience. But if the two have to be connected in parallel, please so note. I also assume that when in series they directly add, or does "dissipationless" resistance have a phase angle associated with it? (And if it does, is the imaginary part "dissipative reactance"?)

Your answers will help me, and I'm sure others, learn how to apply this useful concept. Thanks!

6140. M2 HO Loops: Comments?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-28 19:15:45 UTC
From: Adam Adkins <km5nNoSpam@earthlink.net>
Message-ID: <MPG.152bf4b2d353fa5b989687@news.earthlink.net>
Source record: 167314

I have been giving some serious thought to upgrading my VHF / UHF antenna array. There are a couple of conditions I want to satisfy:

Resonable cost - Obvious enough. I am not interested in spending great wads of cash, and don't particularly care to build one at the moment. My building efforts are going toward other projects, besides antennas.

Ease of erection - Small windload, light, short turning radius. I have a small rotator on a push up pole, about 35 feet.

Versatile - I do not seriously chase weak signals on higher frequencies, but might want to consider it in the future. Current use is local repeaters, CW, SSB, and packet. I will want to try satellite at some future time.

With all of that in mind, I discovered the M2 HO loop series, and they look very slick. They might not be all that well suited for satellite work, but seem to satisfy everything else exactly. Even better, they are advertised for just shy of 9 dB gain when stacked in phase.
My question, then, is "Has anyone actually used them?" I am very interested in feedback from those who have.

Thanks for reading. My apologies in advance for the spam blocked address.

My first publication ever in QST was the first of seven installments of "Another Look At Reflections" (the fore-runner of my book "Reflections, etc"), which appeared in the April 1973 issue.

My concepts of wave mechanics on transmission lines in that article were so foreign (and even hostile) to some of the readers they thought it was the annual QST April Fool's story. Some of the responses to that effect were printed in the 'Correspondence' column. Some were not amused by my heretical idea that power can flow in both directions simultaneously on a transmission line.

My 1972 presentation was serious---could it be that Peter's imaginary jR is not?

Wes Stewart, N7WS wrote:
Why?

Nice call, Wes. In the near field of an antenna, the induction fields are not equal, in phase, nor do they decay at the same rate. Their relative strengths depend on the distance from the radiator.

As I said on Mar. 22, 2001, 9:16 am, the electric field declines as the sixth-power of the distance, and the magnetic field declines as the fourth-power of the distance.

Should you be very close to a noise source its electric field would be very much stronger relative to the magnetic field than would be obtained at greater distance.

So, when you happen to be close to a noise source, a Faraday shield on your loop may help the S/N ratio by eliminating electrostatic (which really means electrodynamic) coupling between the noise and the loop.

For loops in general, Terman says:
"The susceptibility of antennas to locally generated noise varies. In particular, a loop antenna responds much less to the induction field than does a simple wire antenna of comparable intercept area." (page 929, 1955 edition)

I don't like the paragraph very much. It's incorrect at worst, and misleading at best. If you want to increase the current in your antenna without changing the antenna physically, there's only one way to do it: increase the power you deliver to it. To double the current, you need four times the power. No fiddling of the feedpoint impedance, resonating, or anything else you do will relieve you from this requirement.

Suppose you apply 100 watts to an antenna that has a feedpoint impedance of 100 + j100 ohms. How much current flows at the antenna feedpoint? (Answer: 1 ampere.) Then you tune out the reactance by adding a series capacitor having 100 ohms of reactance, making the feedpoint impedance 100 + j0 -- resonant, and again apply 100 watts. Now what's the current? (Answer: 1 ampere.) The Antenna Book paragraph implies that resonating the antenna would increase the current. But it doesn't.

The current would increase only if you were feeding the antenna with a voltage source. A rig isn't a voltage source, but let's see what would happen if it were. Say, 100 volts. You hook that to your 100 + j100 ohm antenna and get 0.71 ampere. The source has to deliver I^2 * R = 50 watts. Then you tune out the reactance, making the antenna 100 + j0. The current is now 1 ampere. But the source now has to deliver 100 watts. So you've increased the current by the square root of 2, but you've had to put twice the power into the antenna to do it. The relationship between antenna current and applied power is I = sqrt(P/R), where R is the feedpoint resistance of the antenna itself, regardless of the kind of source you have and any transformation of the feedpoint impedance you do. You can't get around it. And no fiddling with the reactance will give you more current for a given amount of applied power.

There are, certainly, practical issues involved with delivering power to a highly reactive load, but that's not the topic of the discussion. And while most modern rigs are designed to deliver full power into non-reactive loads, I could just as easily design a rig that would put more power into a 100 + j100 ohm load than into 100 + j0 or 50 + j0. (In fact, you can do it yourself, just by connecting a tuner to your tranmitter, adjusting the tuner for 50 + j0 in when the load is 100 + j100, and calling the tuner/tranmitter combination your "rig".)

Making an antenna resonant, either through matching or by design, won't cause it to radiate more, as the paragraph implies.

Hi Roy:

I enjoyed your post on magnetic fields/loops etc. It was excellent.

Anyway, I won't "fill in the blanks" above but I will respond. I know that you understand what I am going to say so this more of a general discussion . I think this issue is similar to the thread on "dissipation" and "radiation". It all may be a matter of semantics and interpretation.

The first point is defining dissipation. IMHO, I will stick to the definition that dissipation is the conversion of EM energy to heat, i.e.: thermal, IR, etc.

Second is the fact that before we consider power being dissipated in a system, we must first consider that power is delivered to the system. Once delivered to the system, some level of power will be dissipated, some will be radiated, etc.

In RF systems, voltages and currents are generally complex quantities that have an associated magnitude and phase, or a real and imaginary component. With V and I generally being complex, it is incorrect to think of the ratio of V/I as "resistance". In general, the ratio of V/I is impedance which also has a real and imaginary component. We generally define the real component of impedance as "resistance" and the imaginary component as "reactance".

The resistive component of the impedance is not defined by V/I when V and I are complex. It is defined as |V| cos(A)/|I| where A is the phase angle difference between V and I. In all cases, the real power "delivered" to the impedance will be equal to |V| * |I| * cos(A). This delivered power is also always equal to |I|^2 R. (I have seen some hams measure or calculate |V| and |I| in a circuit and then determine "resistance" and power incorrectly by neglecting the phase angle dependence).

So, the question now is what happens to the "delivered" power? Since the total power delivery is found from the total resistance and only a portion of the total power is dissipated, only a portion of the total resistance accounts for "dissipation". Hence the portion that does not account for dissipation is defined non-dissipative resistance (I don't particularly like the term).

This is exactly the same as the case where we consider power delivery to an antenna. Some portion of the delivered power is dissipated when the total antenna R has a component of loss. The component of R that does not "dissipate" power can be thought of as a non-dissipative resistance. There is however, power "delivered" to this non-dissipative resistance. With an antenna, this delivered power is radiated, hence the term radiation resistance.

In free space, I would liken the free space impedance of 377 ohms to a non-dissipative resistance as power flow or delivery occurs but dissipation as heat does not (IMHO).

With transmission lines this discussion gets much more complex. The level of steady state power "delivery" to the transmission line is determined from the input impedance. The level of power flow or travel in the forward and rearward direction are determined from Zo. In a purely lossless system, the real component of Zin could be considered a non-dissipative resistance, only because there is no loss in the system. In a real world system with loss, the resistive component of Zin cannot be considered to be non-dissipative. In a lossy transmission line system, the resistive component of Zin can be used to determine the level of power delivery to the transmission line. The dissipation in the transmission line is determined per unit length from alpha. Alpha is a function of R, L, G and C. Note that R in this case is not Ro (the real component of Zo). In general, most people do not divide the input resistance into a dissipative or non-dissipative component. Note also that the resistive component of Zo should not be considered to be a non-dissipative resistance in a lossy transmission line.

I have not checked it out but was told by an older ham the smaller
Johnson Matchbox was really designed for open wire feeders and does not
work very well with coax feed lines.

I am not big on the MFJ stuff, but if you have to buy a SWR meter then
one of the MFJ tuners that has a built in SWR meter such as the MFJ-948
is not too bad for the money. I recommend it over the similar MFJ
modles if you have a rig without tunig controls. YOu don't need the
built in dummy load some modles have and you really get an extra coax
output jack. The one I have does seem somewhat lossey on 80 meters on
the limitated testing I have done into a 50 ohm dummy load, but not
really too bad.

<Cortland.Richmond@usa.alcatel.com> wrote:

>You have been saying for some time now that one can't separate magnetic and
>electric fields anyway. If true, one could never tel what their ratio was to
>each other.

I've never said that. I said you can not separate the time-varying
magnetic field from the time-varying electric field....you take one to
zero...the other goes to zero.

All the shield on the loop does is become the actual antenna. It does
not change the field impedance of the antenna, nor does it eliminate
the effects of time-varying electric fields.

The shield solves common mode problems (that can also be solved by
balance, because they by definition are balance related).

It's basic, and everyone (with the exception of two people) seems to
agree.

This really is important, because if you understand that one
time-varying field can not exist without the other, and that radiation
is a different effect than the induction fields (both magnetic and
electric), you won't fall victim to nonsense like CFA antennas, the
"Magenetic Slot Radiator" in the antenna compendium, the DDRR antenna,
the Contra Wound Torid bunk, and all that other nonsense.

If a person considers the shield on a loop passes the time-varying
magnetic field at the operating frequency and "culls out" the electric
field, he will run into conflicts between the real world and his
understanding.

Did you read Roy's post, or did he waste his time?

Hi Roy:

It will if the same level of *forward* power is applied to the antenna in each case. This discussion is tricky because it really requires one to clearly define "applied" power. If you maintain the same level of forward power in the transmission line, the level of current, voltage and power delivery at the antenna will change with impedance.

To maintain the same level of delivered and radiated power with an impedance change, the level of forward power will have to be adjusted accordingly. If you were to check, for the same "delivered" power, there will be less forward power in the line with the resonant antenna (in the example you describe).

It sure appears like it is confusing to me! The ratio of rectance to
resistance has nothing to do with antenna efficiency.

IMO, this paragraph is similar to the statement that a dipole antenna
at 5/8 wl height has "gain" because the radiation resistance is lower,
causing more current to flow.

Someone has the cart before the horse.

True that the characteristics of the transmitter and feedline are involved. My response was only reflecting Pythagoras. The impedance of 100 ohms of resistance and 100 ohms of reactance is 141 ohms. If you put 100 volts to that, you get 0.7 amps on an angle of 45 degrees.

If you tune out the reactance, the current is 1.0 amp on an angle of 0 degrees.

Roy is absolutely right. There is no way to increase the current as described without boosting the power.

I don't have any problem with people discussing and arguing about whether power is "dissipated" or not once it passes a particular point. This newsgroup shows that quite a few people enjoy this sort of endless and unresolvable philosophical and semantic discourse. I don't, but it's fine by me.

The point I was trying (and apparently failed) to make is this: A new (to me) quantity has been proposed, "dissipationless resistance". Other quantities I'm familiar with, such as resistance, impedance, capacitance, magnetic flux, electric field strength, force, and on and on, can all be calculated and measured, giving them real meaning and usefulness. If you can't calculate how many ohms of resistance are "dissipative" and how many are "dissipationless", then as far as I'm concerned, you don't have a quantity at all, but a vague concept. And vague it is. Can a resistance be only "dissipative" or "dissipationless", or can a combination exist? If a combination can exist, then how do I, as an engineer wanting to make practical use of this concept, calculate how much of each the resistance contains?

I'm sorry, but if I can't determine how much of a resistance (like the ones in my list) is "dissipationless", then as far as I'm concerned it's a philosophical construct rather than a useful engineering quantity. And the requirement for interpretation and debate over semantic minutia certainly put it outside the useful category in my book. I can get out my calculator and figure out the resistance a circuit contains. But it appears that I'll have to consult the philosophers, IEEE, semanticists, and magi to find out how much of it is "dissipationless". Anybody know any consulting thaumaturgists?

A few years ago the ARRL ran a two part artical comparing the various
antenna tuner circuits that are available. Its very interesting and
well worth looking up.

The old Johnson match boxes were excellent, but like you say, they are
primarly intended for matching to balanced open wire feedlines. The
popular "T" network tuners can match a wet noodle. The problem is
that they also suffer from high internal losses. They make great
advertising copy and that's about all.

The hands down winner is the old Collins 180S1 pi network tuner.
Collins as always "knows RF" and has the simplist and most efficiant
design. I built a duplicate of one using two 500pf transmitting
variable capacitors and a surplus roller inductor. I got the caps as
kits (yes kits!) for $40 each from Ten Tec. The inductor I found at a
hamfest for $20. The rest switches, fixed loading caps, etc. came out
of the junk box. BTW, you don't need a fancy box for a tuner. I've
built them on a wooden board and they worked just fine.

Bottom line, avoid the cheap stuff, if it sounds too good to be true,
it is! You can build a tuner for a fraction of what one costs
commercially. If you do want to buy one, check out the new "L"
network tuner of Ten Tec's. It will do most of what the old 180S1 did
and is available now. BTW, Ten Tec like Collins "knows RF," and their
equipment is very robust and repairable. I have their HF rig and it
is fantastic.

>73's de KB3CDF

Dear John,

I tried a through the window antenna on my last new car. That type of antenna is absolutly junk! I removed it from the car and replaced it with a hole mounted dual band (2M/70cm) right behind the sun roof. BTW, the car is Nisson 240SX. The dealer told me that the antenna hole had absolutly no affect on the trade in / resale value. They simply stick a cell phone antenna in its place and that is the end of the story.

Mag mounts have their own problems. Expect that you will replace the RG-58 coax frequently. Closing the car door on it will destroy it. Plus even with a pad under the magnet, the magnet will slowly damage the finish of the car's roof. Bottom line, drill the hole and enjoy mobile operation.

That isn't true Dave.

T network tuners are very efficient at most load impedances people will run into. They are no worse than any other configuratation.

>The hands down winner is the old Collins 180S1 pi network tuner.

Pi-networks and L networks have the most restricted matching range of any configuration. They are no more efficienct than a T using similar components.

>Collins as always "knows RF" and has the simplist and most efficiant >design. I built a duplicate of one using two 500pf transmitting >variable capacitors and a surplus roller inductor. I got the caps as >kits (yes kits!) for $40 each from Ten Tec. The inductor I found at a >hamfest for $20. The rest switches, fixed loading caps, etc. came out >of the junk box. BTW, you don't need a fancy box for a tuner. I've >built them on a wooden board and they worked just fine.

Maybe for your load impedances, but not most people! I exclusively use T networks here when feeding unknown loads.

Assuming resistive loads, the impedance limits of a pi-network tuner with 500 pF capacitors is:

No load less than ~600 ohms on 160 meters.

No load less than ~180 ohms on 80 meters.

No load less than ~50 ohms except on 10 MHz and above.

I didn't bother with ten meters, because I don't know the minimum C of the capacitors or the minimum L of the inductor. It is safe to assume it would have a restricted matching range on ten meters for high impedance loads.

Of course if the impedance presented at the tuner by the antenna system is close to 50 ohms R and has the equivalent of series capacitive reactance, you can null the capacitance with series

inductance and match low impedances, but that would be more luck than planning.

The real reason T's are popular is they match the widest range of impedances with the best results on the widest range of frequencies of any network configuration.

As I read what I posted, another problem jumps at me. I quoted Terman: "----a loop responds much less to the induction field than does a simple wire antenna----."

It dawns on me that some readers may equate "induction field" with magnetic field when that is not Terman`s use of the term. Terman is referring to the reactive near field, includng the electric field and the magnetic field. There must be a word shortage, that words must have so many multiple meanings.

James- as usual, you will get some MFJ bashing on this subject (that is some peoples hobby) , but- having owned several, and now owning two, I have had nothing but good luck and results with the MFJ tuners. One exception was a case where , as it turns out, someone had sprayed a lacquer on the back, and I could get not contacts on the balanced wire connectors, until I scraped them clean. (It sure kept the metal from tarnishing, though)
MFJ has manuals available, and descriptive data on MANY tuners at www.mfjenterprises.com. there are always a large number of tuners, of all brands, on ebay- just search "antenna tuner"- (leave off the quotation marks, and dont use the plural.) They average 40 to 50 listings.

Good luck- Bill-W4BSG

Roy has my point right on! I know what the author was trying to say, but I do not like the way he said it. In other words, I don't think the reader should have to know as much as the guy writing the book to understand what is being said. What happens when the reader gets to a topic where he is weak? Then it is vitally important to be able to trust that the author's presentation is rigorous.

The case above deals with an almost trivial application of the general form of Ohm's law, I=V/Z, Z=R+jX. When X=0, current is maximum and maximum power is delivered to R. But in the section quoted, the author misleadingly fixes the delivered (real) power as he varies X. In so doing, he implies that for the same power delivered to the antenna you can increase radiated power by tuning out the reactance - not so.

A similarly discouraging issue exists in the Antenna Book when they talk about "charges" traveling along the entire length of an antenna during an RF cycle - doesn't happen.

Thank you all for responding.

Paul

6167. Beta match

Newsgroup: rec.radio.amateur.antenna

Can anyone point me to a good description of how a beta match is supposed to work ? I've looked at the description given in the ARRL Antenna Handbook (14th edition - latest one I have) and I understand that the basic theory is that the beta matching section effectively appears as an inductance in parallel with the (slightly capacitive, low resistance) antenna input impedance, and effectively raises the impedance to match 50 ohms. Problem is, if I do some quick calculations with typical values eg an antenna with an input impedance of 20-j10 ohms, I can't find a value of parallel inductance that will raise this to anywhere near 50 ohms. On the other hand, I run a Hy-Gain Explorer 14 which happens to use a beta match, and it gives a good 50 ohm match on all bands !

John- Back in the seventies, when "CB" was not such a bad scene, I mounted an antenna on the top of a dodge van. I put one of the "Lift and foldover" type antennas on a mount cut through the roof, just behind the drivers position. (I should have centered it, but- what did I know?)

I never had a problem with the hole or the mount. My Brother-in-Law has the van now (19 years old) and it still does not leak, at least at the antenna mount.

> to kill people.

Oh, come on. Surely even you can see the difference. A gun can be used by an individual for self-defense, recreational shooting, hunting, and so forth, in addition to it's use as a weapon in warfare situations. A thermonuclear device, on the other hand, is strictly a weapon of war - it cannot be used by an individual for self-defense, hunting, or anything else not related to warfare. In other words, these are not at all in the same catagory (hince are not treated the same when it comes to the law).

> Now, it would seem to me that the very same
> amendment you guys are pulling in the case of
> handguns, rifles and automatic weaponry must
> cover *all* firearms.

Again, handguns, rifles, and automatic rifles or handguns, can all be used for self-defense, hunting, and recreational shooting. And, yes, contrary to the opinions of most anti-gun advocates, an automatic can be used for hunting. In fact, the primary appeal of the automatic is that it can fire a single round in hunting situations, but can also be used an automatic when needed for self-defense. And both modes offer value for the recreational shooter (target practice, competitions, etc). Therefore, it is perfectly reasonable to say that all of these should be covered by that amendment.

Now, perhaps you can answer a question I have about anti-gun advocates. The clear goal of these people is the total elimination of private gun ownership in this country. At the same time, most of very these same people also tend to be anti-police - they often advocate a reduction in the number of police and advocate restrictions on police authority and activities. It these two agendas are accomplished, exactly who is going to defend my family? Are you, an anti-gun advocate (and most likely an anti-police advocate), going to do it?

Actually, if a Z0-match is achieved (by an antenna tuner, for instance)
the forward power becomes a dependent variable and all the power
delivered by the generator is delivered to the antenna system because
the generator sees no reflected power. I think this is probably what Roy
had in mind.

Something I've always wondered - If the load is 50 ohms, a pi-net
tuner can be tuned for absolute minimum series inductance. Seems
under the same circumstances, a T-net inductor would be lossier.

Richard:

It is critical to define "applied" power in the example. If the same forward power is applied to the antenna in both cases, the current will increase when the reactance is tuned out in the example Roy describes. As a result, the power "delivered" to the antenna will increase. I am assuming of course that a transmission line is connected between the transmitter and the antenna.

Steve

Neglecting losses in the transmission line, I agree. In this case, the
forward power increases to compensate for the change in mismatch at the
antenna.

For a single parallel component to be able to match 50 ohms, the
conductance must be 1/50 to start with. The conductance of 20-j10
is 1/25 so a parallel inductance will bring it to 25+j0 ohms.

The conductance of 20-j24.5 is 1/50 so you would need to add -j14.5
ohms in series (a capacitor) before you add the parallel inductance
to bring it to 50 ohms.

Hi Roy:

No problem from my end. In analyzing practical systems, most engineers do
not concern themselves with the concept (IMO).

Take care,
Steve

The transmission line is part of the antenna system so losses don't
have to be neglected for my statement to be correct.

That's true, in the case where a tuner is not needed, a direct short
from the input to output will have lowest loss.

But in that case it is not a network.

So what you are saying is the lowest loss network is a direct zero
resistance connection. That makes perfect sense to me...except it
isn't a tuner. It's a short.

We are dealing with legislation in both cases, and legislation is never written in stone. Just as slavery was legal one day and illegal the next one, the same thing can happen to the "right to bear arms". Surely there is such a thing as a constitutional procedure to repeal amendments.

Well, as long as we're swapping life stories, I'll admit that I've always been sorry that I did not have a shotgun when a burglar broke into my apartment some years ago (while I was in it). Not because he broke in and tried to rob me in order to feed his habit, but because the son of a bitch came back that night and set the balcony on fire and we almost got burned alive.

Do you guys read the damn thing to the end before you hit the Reply button, or what? Both you and Dwight called me an "anti-gun" advocate even though I clearly stated in my previous message that "I do support a right to bear a handgun or two".

> I have absolutely no intention of killing anyone with
> a gun, but I also have no intention of allowing you to confiscate them.

Fine, I have absolutely no intention of killing anyone with a TND, but I also have no intention of allowing you to confiscate it. Let's assume I have one, for the sake of the argument.

> I DO have an intent to use them - the mere existance and presence - to

How the hell you gonna trade it if and when you lose it? Your statement is paradoxical: on one hand you're saying that it is not in our interest to retain as much spectrum as possible, and on the other that we need to trade it. Even so, I got your point and I happen to agree with it - I would gladly give up MHz's of UHF/SHF allocations for expanded HF bands, but the only problem is that people who are willing to pay gold for UHF have nothing to offer in return - they don't own any HF and they don't care for it, unless one day 80 meters becomes the best bet for cellphone use.

6190. Re: Misleading Statement in Antenna Book

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-29 10:04:18 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3AC308A2.DCF09C64@eznec.com>
Source record: 167264

Hm. I thought that "power delivered to an antenna" was unambiguous. What I mean is that if 100 watts is delivered to an antenna, 100 watts is consumed by the antenna. This consumption consists of a combination of heating and radiation. That isn't "forward power", "reverse power", "reactive power" or "non-dissipative power". It's Re(VIconj), I^2*R, V^2/R.

Let's connect a transmitter directly to an antenna whose input impedance is 50 + j0 ohms, and adjust the transmitter to deliver 100 watts. Now put a half wavelength 50 ohm line between the transmitter and antenna. The transmitter still sees 50 + j0, and still delivers 100 watts. The "forward power" on the line is 100 watts, equal to the delivered power, and the "reverse power" is zero. The antenna current is 1.41 amps. Now replace the line with a half wavelength of 450 ohm line. The transmitter still sees 50 + j0 ohms. The delivered power is still 100 watts. The antenna current is still 1.41 amps. The antenna radiates just the same amount as before (namely, 100 watts less loss). But the "forward power" on the line is now 500 watts, or five times the delivered power, and the "reverse power" is 400 watts. I can get you just about any "forward power" you want without changing the power the transmitter has to deliver, the power delivered to the antenna, or the antenna current. In fact, I can hook several half wave lines of different impedance together and have a different "forward power" on each one all at the same time. So there's no fixed relationship between the "forward power" on the line and the antenna current. (Or between the "forward power" and the delivered power.) On the other hand, there's a definite and fixed relationship between the delivered power and the antenna current, namely I = sqrt(P/R).

I agree with Steve. In 25 years as a test equipment design engineer, I never heard the term. I also never encountered a design engineer who didn't understand what resistance was, how it was used, or what it meant, or who needed some other "kind" of resistance in order to understand it. I do admit that I spent most of my career working with what I've since discovered to be an exceptional group of people, so I suppose it's possible that there really are some confused folks out there who need more kinds of resistance. But if there are, let's give them something they can calculate and not just something to debate about.

Thanks! Is it still a non-dissipative resistance if the cable is terminated with a 50 ohm resistor? Or in that case do we have a dissipationless characteristic resistance but a dissipative input resistance, making the input resistance and characteristic resistances equal in value but different in kind?

By which law of physics or by whichmathematical formula did you arrive at that result? Maybe you measured it on your dissipationless resistance meter?

Let's see was it Ohm's Law, Snell's Law, Kirchoff's Third Law, Sadi Carnot's Second Law...?

Or perhaps or perhaps you used one of the Laws enscribed upon the Tablets presented to the founder of "The Church of Dissipationless Resistance".

In addition to having ac and dc voltage and current scales on it's face, my VOM has only one scale on it for resistance. Maybe Tripplett, or Fluke, or AVO, or... forget to add the dissipationless resistance scale to their meters? What?

That woulda been a real breakthrough to add the capability to measure dissipationless resistance to a meter don't you think?

Gimme a break... dissipationless resistance is another one of those silly religious "crocks" and ya'll know it! And... I ain't goin to drink any of that coolaid ya'll keep mixing up for me, even if the world is goin to end tomorrow!

Long live hard Science and Mathematics, thank God for giving us those immutable subjects to support our "fuzzy" thinking.

Dissipationless Resistance indeed! Pshawww!

>

Hi Roy:

Just my 2 cents worth again.

There is a fixed relationship between forward power and delivered power.
There is also a fixed relationship between the forward power and the antenna
current. These fixed relationships are established by the reflection
coefficient of the antenna. The forward power is a lossless transmission
line is always related to the delivered power as follows:

PFWD = PDEL / (1 - |rho|^2)

In the example you describe above with the 450 ohm line: If the delivered power is 100 W, the forward power is 277.78 W. If 100 Watts of power is delivered to a 50 ohm antenna through a 450 ohm line, the forward power will always be 277.78 W regardless of the line length. If there is no tuner internal to the transmitter, the transmitter will have to be manually adjusted to maintain this 100 W of delivered power as the line length changes.

To maintain a constant delivered power to an antenna with changing impedance, there must be an external compensation or power adjustment. This compensation can be implemented with a tuner through establishing an impedance match at the tuner input. If no tuner exists in the system, then the output levels of the transmitter must be adjusted.

But the point is that a pi-net tuner is capable of a near short
and a T-net tuner isn't (unless there's a bypass switch). With
all three components at minimum values, the pi-net is low loss.
With all three components at maximum values, is the T-net low
loss? I'm not saying it isn't - I'm just asking.

Tom, W8JI wrote:
"All the shield on the loop does is become the actual antenna."

A conducting surface enclosing an r-f coil, antenna, or some other electronic device, (remember tube shields?) shields it. The shield tends to keep r-f in or out of the enclosure. The shield does not need to be a solid continuous sheet enclosure to act as a terminus for nearly all electric field lines of force which approach its surface. But, a shield with gaps is not so effective at blocking magnetic lines of force.

These phenomena are perfected and exploited in the Faraday shield, and used to cut off electric flux without simultaneously affecting the magnetic field.

Yes, the electric and magnetic fields are separable no matter who says they aren`t, or how many times they say it.

See Terman`s "Electronic and Radio Engineering", 1955 edition, page 38.

The Faraday shield is made by surrounding the space to be shielded with a conducting cage, Elements of the cage are conducting bars or wires, connected and grounded at one end. At their other end the bars or wires are insulated from ground and each other.

This construction prevents any significant magnetically induced currents in the shield. By Lenz`s law, the induced shield current if allowed to circulate over a wide area would produce a commensurate magnetic field opposite to the inducing field. This circulating current if not banned by the bars or wires would end the progress of the magnetic field lines through the shield. In the Faraday shield, the magnetic lines go right through but the electric field lines don`t go through the shield.

The Faraday shield is an effective separator of magnetic and electric fields at its surface.

No one says that the magnetic field passing through the shield does not immediately generate a new electric field as the old field is ended at the shield.

Whatever disproportionate unwanted perturbances existed on the old electric field, they are terminated with the old field on the shield. That is why Faraday shields are widely used.

No reason has been offered by Tom to support his claim that Faraday shields are only good to balance capacitances.

Tom is dead wrong.

Best regards, Richard Harrison, KB5WZI

Yep, the repeal of slavery took a constitutional amendment and the repeal of
the right to bear arms will take a constitutional amendment. If guns are outlawed,
unarmed citizens will be absolutely helpless against armed criminals who don't
care about gun laws. England is doctoring her stats to try to hide the fact
that their armed criminals are out of control. If an armed perp gets off on
a technicality, that crime is erased from the stats.

In this country, guns have always been used for more good than evil. The
liberal press simply doesn't report the good done by guns. Gun laws will
disarm the good guys and leave the bad guys armed - bad idea.

My IC751A will run more power into an 80 ohm load than into a 50 ohm load. Suppose the feedline presents 80 ohms j0. I don't need a tuner then..

My DX-100 will deliver full power into a 450 ohm line, with no external tuner.

If I build a meter that is normalized at 450 ohms and measure power in a 450 ohm line terminated in 450 ohms j0, the forward power will be 100 watts and reflected power zero watts. that is true no matter what transmitter impedance I have.

If I make no changes to the system and measure power with a meter normalized to 50 ohms, the forward power will be higher and reflected power "suddenly appears".

If I move a 50 ohm meter along a long 450 ohm line terminated in 50 ohms, I'll find points where reflected power is zero watts. I'll see the forward power varies all over the place.

Why does the forward power return to normal when I measure it with a meter normalized to the impedance of the line at the point where I measure, if there is really all that extra power in the line?

It amazes me how people take models that are meant to make life easy as the way things actually work.

> equal in value but different in kind?

If the voltage and current are in phase at a point and there is no dissipation taking place at that point then the resistance at that point is, by definition, dissipationless, i.e. zero dissipation.

If a 50 ohm resistor is the load for a 50 ohm lossless line, the dissipation is taking place in the resistor, not in the line, so the 50+j0 characteristic impedance is dissipationless. The same power simply cannot be dissipated in two completely different places.

If all the power is dissipated in the load, then none is dissipated in the line even though, in the line, the voltage and current are in phase. As far as I can tell, in this example at least, everything is 100% consistent.

In the real world the limits of the components always prevent perfect
devices.

The T is a mirror of the pi. If you could set all the components in a
T for maximum values, it would be the same as setting all the
components in a pi for minimum values.

The ideal network would probably be one that allows the same
components to be switched from a T to a Pi.....but that won't happen
because of complexty.

But all of this is beside my point.

My point is the pi network offers the LOWEST impedance/frequency range
of any network configuration with given components, and that is why
they have fallen out of favor for antenna tuners.

It isn't that people are stupid, or cheap, or bad engineers and
foolishly select a T network out of pure unvarnished stupidity.

The truth is simply that dollar for dollar you get the widest matching
range, best overall efficiency, and power handling from a T network.

> meter?

It's the principle of conservation of energy. If the RF energy out
of a transmission line equals the RF energy into a transmission line,
then even though the current and voltage are in phase providing a pure
resistance at any point of measurement in the line, that measured
resistance is dissipationless. You simply cannot dissipate (RF to heat)
the same power in two completely different places. You have 50 ohms
resistance existing at an infinite number of points in the transmission
line yet no power is dissipated in the transmission line. It doesn't
take a rocket scientist to figure out that the resistance measured in
the transmission line is dissipationless cuz the load got hot and the
line didn't.

6207. A question about Transmatches - Please wiegh in!

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-29 15:37:36 UTC
From: Paul <pvanasse@mail.direcpc.com>
Message-ID: <4FIw6.21831$PR.181354@news1.wwck1.ri.home.com>
Source record: 167179

As I understand it, a transmatch is a two-fold device that variably adjusts Inductive Reactance on the transmitter side, and Capacitive Reactance on the feedline/antenna side of a station. When the feedline impedance equals that of the antenna, the antenna is supposedly purely resistive and it becomes an electrical load, which feedline capacitive reactance should be near zero. The load (antenna) then distributes 100% of the energy supplied from the feedline whereas zero energy can return back to the transmitter (1:1 match) because the coax outer shielding and center conductor are phased 180 degrees apart, thus canceling any energy emanating from the coax itself further insuring the distribution of energy to the load.

Here are my questions:

1. If one were to install a transmatch in feedline system that already has an antenna that is purely resistive (1:1 match) what would be the insertion loss in dB resulting from the insertion of this device? Ive never really thought about it until recently.

2. What is/Is there a linear relationship of insertion loss resulting from the transmatch installation in relation to the inductive reactance present at the transmitter? i.e.. At what point are you better off having the radio fold back somewhat as compared to the insertion loss incurred by the installing a of transmatch?

Thanks and 73

Tom, W8JI wrote:
"I`ve never said that. I said you can not separate the time-varying magnetic field from the time-varying electric field....you take one to zero....the other goes to zero.'

Weasel words, Tom. The meaning is clear when discussing r-f coupling that magnetic and electric refer to r-f. It isn`t needed to continuously define r-f as time-varying.

You certainly can separate the magnetic and electric components of r-f. Millions of examples are at use at this moment in the Faraday shields in transformers, broadcast antenna systems, and shielded loops.

You can take one to zero without killing a signal. Example: Two coils in separate tight shield cans. A tiny hole in each allows interconnection through a capacitor and disallows magnetic coupling. Vigorous representations of the signal exist in both cans though the signal originates only in one. Another example: Two coils are aligned on the same axis on opposite sides of a Faraday shield. The shield kills the electric field between the two coils yet allows magnetic coupling. It works! It works!

In both examples, the missing field is immediately generated by the remaining field which makes the trip to the second coil.

Tom is dead wrong.

Best regards, Richard Harrison, KB5WZI

The 277.78 W of measured power assumed a Zo wattmeter.
A 50-ohm wattmeter measuring the same forward traveling voltage would
indicate 2500 W of forward power.

If you measure 100 W of forward power with the 450-ohm wattmeter, you will
measure 2500 W of forward power with the 50 ohm meter. I assume they both
measure the same forward traveling voltage.

If the 450 ohm line is terminated in 450 ohms, there is no rearward
traveling voltage or power. How does a meter of any impedance translate 0
volts and 0 amps into real power?

Source record: 167184

I bought a used Heath SA 2060A, and I've been very happy with it. The Heath replaced my MFJ-941E, which is now just a tuner for a shortwave receiver. These two tuners are on opposite ends of the spectrum. The MFJ had a low power handling capacity and fixed inductor positions. The Heath handles a full gallon (or so the book says) but has a fully variable inductor. Inside, the components are very heavy duty looking. With the MFJ, I always felt that the optimum position was "in between" the fixed positions. With the Heath tuner, I am able to tune up everything I need. This is not a bash on MFJ, the comparison would well be accurate for any similar tuner.

So, I would agree with others who have posted, get a tuner with the widest range, and as much power handling ability as possible. I had lots of arching problems with the smaller MFJ and I've had none with the Heath. I also did not personally like the crossed-needle meter on it. The Heath has dual meters which read SWR and power output - very convenient.

And if price is an issue (as it was for me) get a used tuner.

The fixed relationship is Pdelivered = Pforward - Preflected.

The fixed relationship is Pforward = Pdelivered / (1 - |rho|^2)

Change anything you want to, these relationship do not change.

That's not a fixed relationship. That's a variable relationship.
That relationship depends on the independent variable rho.

How true. When I went to school in Los Angels areas of California in the 60's and 70's almost every kid I knew had access to a firearm at home. Back then you could buy a gun over the counter at Sears, Montgomery Wards, JC Penny, Pep Boys, True Value Hardware, etc. cash and carry. You had to be 16 to buy a long gun, and 21 to buy a pistol but there were no laws against your parents buying you a pistol if they wanted to.

Many of the kids I went to school with were regular hunters and outdoorsmen along with their fathers, uncles, etc. I had three younger siblings and we all had our own rifles which our parents gave us as Christmas presents around the ages of 10 or 12.

There was never a firearms related incident in any of my schools, or even in my neighborhood (unless you count the time one of my neighbors shot some low-life who was trying to rob the local shoe store during the original Watts Riots).

There were also no drug dealers and gang bangers on every corner when I was in school. The record companies would never dream of putting out any of the "Cop Killer" Rap music which is present today - and the kids' parents would kick their butts if they ever tried to bring that kind of crap home.

The police were allowed to actively suppress crime rather than just reacting to it after the fact, but now days every hoodlum is taught at a young age "I know my rights, I'll sue you for ..." And parents are regularly prosecuted for "Child Abuse" if they try to make any attempts to prevent an out-of-control juvenile from running wild on the streets.

Yes, we have a big problem these days in the schools - and in society in general - but it is not, and has never been, a gun problem. It's a people problem, and as long as nobody in power has the "brass" to address it for what it is, it will only get worse...

Source record: 167193

It seems like months ago now, but I quoted numerous experts who say a Faraday shield works.

I`ll relist some: Terman, Griffith, Dean, and Christiansen. I referenced the work of others:
Stanford Goldman, "A Shielded Loop for Noise Reduction in Broadcast Reception", Electronics, Oct. 1938, pp 20-22, Dudley E. Foster and C.W. Finnigan, "A Method of Measuring the Effectiveness of Electrostatic Loop Shielding", Proc. IRE, June, 1943, pp 253-255.

So many experts! They are all wrong and Tom is right? Don`t bet on it.

Best regards, Richard Harrison, KB5WZI

I simply meant that there is a defined relationship between Pdelivered and Pforward. Obviously, as rho changes, given a fixed Pforward, the delivered power changes. Delivered power is the end result of the process of how the forward power develops.

Lately, discussions on the NG seem to be more focused on word definitions than concepts. I will have to choose my words and phrasing very carefully.

Hello Readers

I currently own a GP9NC Antenna for my scanner radios and am looking at getting another for my ham radios. The GP6 has been recommended to me and I was just wondering if I would be able to mount the GP6 on the same mast as the GP9NC or would it cause interference and "burn" the GP9 out?

Let me know

>
>Paul, VE3ICV

This is basically an L-network problem. The (typically) lower feedpoint resistance (Ra) of the driven element is transformed to the higher value of the real part of the transmission line characteristic impedance (Ro) as follows:

Using your number, Ra = 20

Assuming a 50 ohm line, Ro = 50

Determine Q = sqrt ((Ro / Ra) - 1) = 1.225

Then the shunt reactance (inductive in this case) is:

L = Ro / Q = 40.825

The series (capacitive) reactance is:

C = - Q * Ra = -24.495

So the driven element must be shortened from resonance to present a ~24.5 ohm capacitive reactance and the stub must be adjusted to provide ~41 ohm of inductive reactance.

I believe that your confusion results from not changing to the proper equivalents when doing your analysis. Remember that the feedpoint impedance is just that; an impedance, i.e., a *series* equivalent. However, when you shunt the transmission line with the inductive stub, you must do it in the *parallel* form, i.e., as an admittance.

So the line plus stub combination is:

G = 1 / Ro || 1 / 40.825 = 0.02 - j 0.0245

Converting back to series form:

Z = 1 / G = 20 + j 24.495

This series equivalent is the conjugate of the (adjusted) feedpoint Z and you have a match.

Some years ago I heard several references to a "snake antenna" being used for portable operation. It was said to be just a length of coax that you unrolled on the ground. I don't remember whether it was terminated in some way or not, cut to resonance or whether some sort of tuner needed to be used.

Has anyone heard of or used anything like this? Any comments plus or minus would be appreciated. I'm down to last resorts in an antenna restricted area.

6226. Re: Faraday shield antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-29 20:30:33 UTC
From: Cortland Richmond <Cortland.Richmond@usa.alcatel.com>
Message-ID: <3AC39B69.4983F723@usa.alcatel.com>
Source record: 167200

Point of view seems one of the issues we have been having (and avoiding) here.

The electric field component of a signal incident on the loop is vertically polarized. If I shunt that field (I used the example of a metal roofed porch) I have effectively eliminated it; a short rod antenna sensitive to the electric field will indeed indicate a reduction of signal under a grounded roof. But a loop antenna will still show the same level of signal it did outside. This is indicative of its responding to something other than the vertically polarized electric filed I have shunted.

The experiment of placing an entire (small) radio with electric probe antenna inside a conducting tube shows that the electric field does not much enter the tube; placing a loopstick-equipped radio inside shows that a signal can still be received. This is indicative that the grounded roof example is carried over in the example of conducting tube.

I don't argue that electrons are accelerated by an electric field. But it isn't impossible that they can be accelerated by a magnetic field, for permanent magnet generators would not work unless they could be.

Given that there are always orthogonal counterparts to the electric or a magnetic component of the electromagnetic field, then there has to be an electric field inside the shield, associated with electrons accelerated by the magnetic component of an incident electromagnetic field. But it's a different electric field than exists outside, as is demonstrated by the fact that electrons are still made to flow in the loop conductor even when we shunt the external electric field.

It seems likely to me that these differing viewpoints explain some of the conflicts we have been having in this thread.

It wasn't bad if you had a 2:1 swr. That is not very far from 1.5:1. The
balun just had a slightly different tranformation ratio. They will tell
you it's good, which it is most likely. You can shift the feedpoint of
the antenna to get a good SWR. MK

Steve is correct that on the 450 ohm line terminated with 50 ohms, the forward power is 277.78 watts, not 500 as I had stated. (The reverse power is 177.78, not 400.) I neglected to take a square root when I should have. Thanks to Steve for pointing out the error.

I also agree with the facts in the remainder of Steve's posting. We seem to have a different interpretation about the meaning of a "fixed relationship", however. But I still retain my opinion that the Antenna Book article is misleading at best. A determination of its factuality shouldn't have to depend on a discussion of forward and reverse power, reflection coefficients, line lengths, and impedance matches.

Source record: 167205

Thanks again, now I'm getting the hang of it. If I measure the resistance of a leaded resistor by connecting a meter to the resistor's leads, it's dissipationless resistance because there's no dissipation at that point, in the wires. But if I connect the leads directly to the resistor body or if I measure a surface mount resistor, it's dissipative resistance. To make a model of a leaded resistor, then, it looks like I need a new component -- a resistance "converter". I start with a "dissipative" resistor, then connect a "dissipation converter" in series, then model the leads. That way, anything connected to the leads sees a "non-dissipative" resistance, but on the other side of the "converter" it's "dissipative". Do I have the right idea?

But I'm still confused about that amplifier transresistance. Maybe you can help out with that, too.

6232. G5RV problems

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-29 21:52:37 UTC
From: "Dave Cook", com
Message-ID: <F8Ow6.642973$U46.19745922@news1.sttls1.wa.home.com>
Source record: 167206

I built a 1/2 size G5RV - the ARRL handbook said you could cut the dimensions in half to work 40 - 10. The dipole dimensions were too short, so I had to lengthen them to get resonance on 40 mtrs. It works fine on 40, 20, and 10, and I even get a 3:1 swr on 30 and 12 meters. But 30 (who cares?) and 15 mtrs are way off the SWR meter. Is the G5RV really an "all-band" antenna? Any suggestions on where I might be going wrong? The final dimensions for this one are about 55' for the dipole, 15' for the feeder, a coax choke at the feedpoint, and about 50' of coax feed.

Thanks for any advice,
-- Dave, WA0TTN

>line - approx 250ft run at 3.5/7Mhz at low SWR.
>
Any practical transmission line has two limitations. One is the breakdown voltage, almost always given in line specifications. The second is the current capacity, almost never given. The reason is complex, since (at least) the conditions around the line in the way of air flow, insulation, etc plus the way the line is installed (bend radius, forces on line, etc) plus the length of time the line is in use all are important.

For an estimate, use the allowable current ratings found in wire tables for transformer windings, usually for a 40 deg C rise. This gives for transmitting twinlead perfectly matched 4 KW power capability. Even at SWR=25, the line can handle 800 watts. These are continous ratings, so the handling capability is even greater with CW, SSB.

I've never had a line fail by voltage breakkdown, but have had failures in coax and twinlead due to heating. In each case it was at a bend, where fairly high SWR put a high current point close to the bend. None happened until after some time had passed.

Cortland Richmond wrote:
"Point of view seems to be one of the issues we have been having (and avoiding) here."

A small loop has a directional response like a doughnut with a null through its axis.

A rod has nulls off its ends.

Vertical loops are used to take advantage of vertically polarized waves. If a loop is horizontal, it is responsive to horizontally polarized waves. A small horizontal loop has equal response in all horizontal directions.

A small loop has tangential electric vectors "chasing each other" around the loop.

Small loops are usually vertically polarized because vertical groundwaves propagate well. Horizontally polarized groundwaves do not propagate well. Attenuation is very high for horizontal waves along the ground.

Skywaves have polarizations scrambled by the ionosphere and this is deleterious to directional response by the loop.

Antenna response depends on polarity matching among other factors.

Best regards, Richard Harrison, KB5WZI

Dave,
To answer one of your question, no, it really isn't
an all-band antenna and was never ment to be. It just
happens that it had 'sort of' reasonable 'match' on
other bands ~if~ you used a tuner. What are you doing
wrong? Thinking that your going to get something for
nothing. Sorry 'bout that...

marty,
Works pretty good as a receive only antenna. It was
described as at least 1 wavelength long and terminated
in a 50 ohm non-inductive resister. You don't have a
lot of noise, but you also have 'less' signal to work
with too.

Source record: 167209

I think you have the theory all wrong about the transmatch. Anyway without getting into the theory part a transmatch can loose about 5 to 10 percent of the power if it is working as it should and more if it is not. My MFJ looses about 10 watts out of 100 going into it on 80 meters when fed into a good dummy load and less as I move toward the higher frequencies. The mfj is not the greatest but typical of the inexpensive ones.

For question number 2, The loss is in the feed line from the transmatch to the antenna. Unless you plan on putting the transmatch at the antenna you will have the same losses in the feedline if you do or do not use the transmatch not counting the 5 to 10 % loss in the transmatch. YOu do not want the transmitter to fold back as it is not operating efficently and will put stress on the transmiter circuits and possiably shorten the life of the transmitter. YOu use the transmatch to mask the swr so the transmitter will operate with more efficency.

Hard to say ... they range from MFJ to Nye-Viking MBVA ... quite a
range.

1) not MFJ
2) Vectronic DLP300 is a nicely built, good performing tuner (built by
MFJ now, so I can't say what they're like now)
3) Take a look at LDG Electronics autotuner AT-11!

Look on eham.net for product reviews to see what users think about
their tuners.

Paul,
If the tuner is at the feedline/antenna junction, your
assumptions may be correct. If it's at the radio end of
the feedline, then you have changed nothing about the SWR,
any reflected power in the system before using the tuner is
still there. (system = feedline and antenna)
Never measured the insertion losses, no idea what they
may be, but there will be losses, even if the systemSWR
is close to 1.0:1.

That's correct. The same power cannot be dissipated both in the leads
going to the resistor and also in the resistor itself. Resistor leads
have always been considered dissipationless because there is usually
negligible I^2*R loss in resistor leads. Why is that so hard to accept?

Keeping the load resistance fixed, the input impedance of a balun
will change with frequency and so will the measured SWR. I once
asked Amidon to measure the inductance of one of their baluns on
10m. It was capacitive.

How can a balun do any balancing when one side doesn't go anywhere?

End fed antennas work best when a single wire (not coax) is fed
against ground or a counterpoise. In general, coax should not
be used with non-resonant antennas.

The G5RV is NOT an all-band antenna. The full-sized G5RV works well
with an antenna tuner on 80m, 40m, 20m, and 12m. Follow the G5RV link
on my web page to find out why. That means the half-sized G5RV works
well on 40m, 20m, 10m, and maybe 6m. It is absolutely lousey on 15m
just like the full-sized G5RV is lousey on 30m.

An antenna tuner is necessary for a G5RV except maybe on one or two
bands. A half-sized G5RV would be naturally resonant on 10m, its
designed-for frequency.

Source record: 167123

Tom, W8JI wrote:
"All the shield on the loop does is become the actual antenna."

There is a large difference between the characteristics of the open-circuit shield over a shielded small loop and the characteristics of the closed-circuit inner loop by itself.

The radiation resistance of a small closed loop is 123 times the perimeter in wavelengths raised to the fourth power.

The radiation resistance of a small open loop is 12.3 times the perimeter in wavelengths squared.

The radiation resistance formulas are thanks to Arnold Bailey`s "TV and Other Receiving Antennas". These formulas are for small rectangular loops. For circular loops, the radiation resistances must be multiplied by 1.62 to account for the differences in area between rectangular and circular loops.

The broken loop has currents in-phase in its two halves, similar to a short center-fed dipole. Its directional response is also like a short center-fed rod.

The closed loop has nearly the same current all of the way around. It is after all just a big short-circuit. Viewed from broadside, currents on opposite sides of either loop are in opposite directions. But, current distributions are quite different for the two loops.

The implications are for major differences between the open-circuit Faraday shield and the closed-circuit inside loop, which is shielded by the outer loop, when they are compared as receiving devices.

Best regards, Richard Harrison, KB5WZI

Thanks to Wes and others for providing the explanation. I was trying to get a match to 50 ohms by changing the parallel inductance only. For a given antenna feedpoint resistive component, you have to alter the reactive component too.

The roof becomes the antenna, the field impedance of the antenna
changes. But the electric field does NOT go to zero. As a matter of
fact if the roof has no vertical conducting surfaces you do almost
nothing to a vertically polarized signal.

If you have a small loop under the roof, and remove the roof, you
still have a low field impedance.

A several dozen feet away from the antenna the dominant magnetic field
becomes a dominant electric field.

So what on earth do you accomplish? Nothing.

You don't change the sensitivity to noise in any predictable way. You
don't improve balance in any predictable way.

Naturally if you have a low field impedance structure and you couple
to it with a loop the sensitivity is higher than with a rod antenna
that has been optimized to be in a clear area. I see that when I drive
under wires with my mobile antenna.

>The experiment of placing an entire (small) radio with electric probe antenna

How many dB down did the signal go in each case? Not "At least I can
still hear it".... but how many db? Did the "magnetic field" pass
unattenuated?

If you take the time-varying electric field to zero the magnetic field
will do the same. There is no way around that.

Let me give an example of how a time-varying field can NOT pass through a conductor several skin depths thick.

Some time ago I measured the field on the opposite side of a wall of single sided PC board material. It was about two foot square. It was a wall inside a four sided box seperating the inside halves from each other.

On one side I had a buss wire from a connector to another connector, the far connector terminated in a dummy load the near connector to a 100 watt HF radio.

I made a probe with a small hunk of wire in a dipole for the electric probe, and a small pancake loop for the magnetic field.

The field directly opposite the wall just 1/2 inch or less from the wire was almost zero, and was not even parallel with the wire on the other side. The field increased as I got to the edges, and clearly showed what current appeared on the other side was simply spilling around the edges of the board.

The ratio of electric field to magnetic field was essentially the same on either side of the board, and at any place on the board.

Why didn't the magnetic field go right through the board? Why was it strongest at the edges?

Hi Cecil,

That in itself is a rather simple answer too. It is hard to accept
because when resistance is acknowledged
> there is usually
>negligible I^2*R loss in resistor leads
it is immediately dismissed as negligible (it doesn't exist) to
support the proof of what is being said (even though the statement is
a direct self-contradiction).

Roy, the whole rationale behind this dissipationlessness is to create
the basis for "proving" the internal resistance of generator is
"non-dissipative." What is being swept under the rug, is that this
proof has nothing to do with reality (it is a convention used to
explain a theoretical consideration - not an actual observation).
This illusion is then leveraged to support the misapplication of
Thevenin in non-linear designs (which produce heat in accordance with
already accepted tenets).

The future argument (once dissipationlessness is accepted) is that
when the Zsource is reconsidered, there will be some who step forward
to proclaim, "the R of the generator is dissipationless." Then we
will get into some really contrived proofs of how reflected power is
not lost in the source, because it is dissipationless (in spite of the
heat produced - now try and imagine that!). I can hear some of the
sophistries now: "energy applied in one direction is dissipative while
in another direction it is not!"

As I've said elsewhere, dissipationlessness is the hinge around which
another argument must turn. Frankly, it is a poor application of an
even poorer definition. It has all the qualities of "the tuner fools
your antenna into thinking it is matched to the source." "Fools?"
"Thinks?" Yes these are the same howlers of language that are decried
by technical purists - and yet it is the same sophistication of logic
being pursued here to describe the Rsource as being dissipationless.

It is the straw the drowning pluck at.

Not so.

The shield is NOT an open loop because it is heavily coupled to the inner loop.

It makes no difference at all in field impedance or efficiency if you move the tuning capacitor across the gap in the loop, or across the wire inside the loop.

You don't change a thing by adding the shield except for balance of the system, and changing loss a bit because the "shield" adds conductor length and a large diameter counductor.

Mutual coupling makes the outer loop resonant when the inner one is resonant. Build one, and measure the voltage across the gap sometime. Stop tuning the inner loop, and tune the gap. The impedance is essentially identical, less the loss changes in the capacitor.

Not true.

Wattmeters do not measure voltage alone, they sample current and
voltage. Voltage and phase are summed with consideration of phase
before the RF is detected and converted to dc voltage.

>If the 450 ohm line is terminated in 450 ohms, there is no rearward
>traveling voltage or power. How does a meter of any impedance translate 0
>volts and 0 amps into real power?

A meter normalized for 450 ohms will read zero reflected power and 100
watts. A meter normalized for 50 ohms will, in the very same line
without standing waves, indicate reflected power and "extra" forward
power. If you deduct the reflected power from forward, the result will
be about 100 watts.

There is no magic, the entire transmission line (when in a steady
state) can be looked at without waves and it works out perfectly.

>> If I move a 50 ohm meter along a long 450 ohm line terminated in 50
>> ohms, I'll find points where reflected power is zero watts. I'll see
>> the forward power varies all over the place.
>
>Please explain this.

Get away fromn theory, and look at a wattmeter Steve.

It has two coupling modes. One mode employs a current transformer than
develops a given voltage for a given line current. The second employs
a voltage divider that is across the line.

These two sampled outputs are in series, and the ratios are set so
when line impedance, the across and through vectors, are the correct
ratio (E/I = 50:1 for a 50 ohm line) for the design Zo the sampled
voltages are identical.

Obviously in one direction the volages sum, and if the generator and
load are swapped the phase in the current transformer reverses.

If you design a meter for 50 ohms, and measure SWR while moving it
along a 450 ohm line (or any other line that is NOT 50 ohms) you will
find SWR varies all over the place.

>The statement of mine that you quote above in correct, so please explain
>what you see wrong with it.

Simple. Lets say I mismatch a 450 ohm line by adding a 50 ohm load. If I move the meter along the line, the forward and reflected power will change all over the place. At exact 1/2 wl multiples from the load, the meter will indicate a 1:1 SWR.

The SWR varies along the line.

If I normalize the meter for 450 ohms, the reflected and forward power are constant along the 450 ohm line no matter what the termination.

The SWR does not vary along the line, and only the meter null setting was changed (it could be a pot or trimmer capacitor I adjusted).

If I have a 50 ohm meter, and terminate the line in 450 ohms, the flat line shows a constant ratio of reflected power to forward power along the line and that forward power is the SAME as in a 450 ohm line terminated with 50 ohms measured with a 450 ohm meter.

In either case the meter indicates a 9:1 SWR.

When the meter null is not set for the line Zo, SWR and forward power vary all along the line.

See how simple it is?

Source record: 167128

You could reproduce the results of your experiment by using a capacitor instead of an aluminum shield. Place a capacitor with reactance of, say, 50 ohms from the base of a short whip (feedpoint Z thousands of ohms) to circuit ground and see what happens to the signal. Then put the capacitor across the feedpoint of a resonated loop (feedpoint Z of a few ohms, depending on loss) and see what happens. You'll get the same result as you did with the shield, and the capacitor doesn't intercept any field at all.

If I'm correct about what's happening, you'll also be able to kill the signal to the radio with short whip just by grounding the shield to the radio chassis and putting it close to the whip -- the whip can stay completely outside the shield. If the setup is still handy, it would be interesting to see the results of this experiment.

Source record: 167130

To accept it, I have to understand it and figure out how to apply it. Thanks to your help, my understanding is deepening, and with the new "resistance type converter", I can now model resistors more accurately. Several people have been tossing "dissipationless resistance" around like they know exactly what it is. I'm just trying to get you to pass along what you know so I can also use it with such confidence.

I'm still having a little trouble with the Z0 of a lossy cable. The 50 ohm cable with 6 dB/100 foot loss has a characteristic R of 50 ohms. At any given point along the cable, there's loss. But the Z0 doesn't necessarily represent the impedance at any point along the line; it maintains this Z0 regardless of the load impedance or the impedance seen across the cable at any point. So is the whole 50 ohms "dissipationless", is it "dissipative", or some of each? If only some, how much?

The lack of a response to the question of transresistance is getting noticeable, too. Which pigeonhole does that go into?

Group,

I am looking for input for the best SMALL 160m receive antenna.
It will be put up in an open area (read no trees) and the worst ground
electrical and mechanical that I have found,mostly rock and the water
table at 400 + feet. I have about 1 acre to put this up. I tried a
beverage but it didn't work as well as expected.

That's like asking which mini-van gives the best bang for the buck.

A lot of them do...

I've had good luck with an MFJ 989C. No complaints. Great metering system. Rugged looking components. Whether it's good bang for the buck, who knows?

You really don't have a lot of choices. MFJ makes a bunch of tuners. Ten Tec makes one. Vectronics makes a few. Ameritron makes a couple. Nye-Viking makes one. There's an X-Match tuner that runs over a thousands dollars.

I'd just get an MFJ. When it arrives, take the case off, and make sure there are no cold solder joints. Re-solder them, if necessary. Put it back together... I'd recommend getting one of their kilowatt or plus models, regardless of the power you're running. Your components can never be too rugged.

There's always eBay, but you never know whether those tuners have been hit by lightening or whatever...

Good luck!

An acre is big enough for a Beverage for 10 meters, but a few thousand feet shy for 160. Believe it or not, your best bet for a good receive antenna for 160 is an amplified, shielded loop.

> Thanks for any advice,

For what it's worth this is how mine measures up:

G5RV/2 Frequency -v- Efficiency
1.75 MHz__82.58% Bad reading STRONG QRM, most likely much less than 10%
3.50 MHz__16.55%
7.00 MHz__52.59%
10.00 MHz__17.01%
14.00 MHz__83.69%
18.00 MHz__43.72%
21.00 MHz__14.94%
24.00 MHz__2.46%
28.00 MHz__26.52%
29.00 MHz__22.60%

> how much?

The ratio of the forward voltage to the forward current is fixed at Z0
which is lossless because L is lossless and C is lossless and L/C is Z0.
Any actual losses are due to I^2*R losses and dielectric losses which have
absolutely nothing to do with Z0. Z0 is the same for RG-174 and LMR1700
but the actual losses are quite different.

With a 50 ohm coax transmission line and a 50 ohm load, the 50 ohms
measured at the transmitter end is dissipationless because all the
power is dissipated in the load at the other end. The same power cannot
be dissipated at two different ends of a transmission line so one end
has to be dissipationless.

> The lack of a response to the question of transresistance is getting
> noticeable, too. Which pigeonhole does that go into?

I don't know what transresistance is.

The assumption is that the SWR meter is being used in a transmission
line which has the Z0 for which the SWR meter was calibrated. If that
assumption is not true, then the SWR meter reading is perfectly predictable
but invalid on the meter face.

Okay, in that case you can use thermonuclear device. However, you'll have to limit it's yield, say perhaps to a small tactical device capable of taking out a smaller town instead of the whole city. :-)

> Although, some would say this becomes
> borderline genocide. Like shooting fish
> in the barrell. Like working DX in nets.

Well, that might be true. Of course, it depends on what you're shooting at. My brother-in-law uses an assualt rifle to keep the bears and coyote (wolves, or whatever they are) away from his farm animals in Wyoming. Of course, it is also effective for smaller animals also - he can't hit them, but the sound, and dirt flying up from nearby hits, is enough to scare the holy heck out of them.

> Holy crap, which part of the country do
> you live in? East LA?

Not at the moment (my mother-in-law lives there, though). No, its fairly peaceful where I'm at now, so I mainly use my guns for target practice at the moment. However, when I move (yes, I've been saying that for a year), I intend to move a little further in the woods, and would appreciate having a good weapon around (just for my own peace of mind).

The G5RV has about a 5:1 SWR on 80m. Where, exactly, are the
7.8dB losses?

Absolutely well written, W6DKN. The problem is not guns, or the cars used for joy riding, or the street corners used to sell drugs, or anything else beyond the people involved. Until attitudes change, and we end this seemingly endless tolerance to everything subversive to civilized society, the problems are simply not going to stop.

Z0 is the square root of L/C only for a lossless line. More generally, it's sqrt((R+jwL)/(G+jwC)). In a line with loss, either R or G or both are non-zero, resulting in a complex characteristic impedance. When the impedance is complex, the real part isn't simply sqrt(L/C), as you can see from a bit of manipulation of the more general equation. So your assumptions aren't valid for a lossy cable. Nonetheless, are you saying that the real part of any line's characteristic impedance is "dissipationless"?

When a cable has loss, not all the power is dissipated in the load. Some is dissipated in the cable.

It's the voltage at the output of an amplifier divided by the current at the input.

D.C. has NO law banning handguns. It is not possible to get a concealed carry license but this does not pertain to private property.
Concealed Carry : There is no permit system to acquire a permit to carry a hidden handgun.
Purchase Limitations : Washington, DC has no purchase limitations.
Licensing : All firearms must be registered with District law enforcement.
Possession By Minors : Must be over 21 to obtain permit. However, an 18-21 year old may apply with parental consent.
Gun Storage : There is no Child Access Prevention (CAP) or safe storage laws in the District.
Waiting Period : The Chief has 60 days to approve or deny an application for a registration certificate

The trade would be by/with the FCC, not other users. The Amateur Radio
Spectrum Protection bill that has been kicking around in congress for a
few years says something to that effect, not that it will ever actually
become law.

No one's taking your guns away, Dick. If we lived in a perfect world where everybody's happy and friendly and lovey-dovey, there would be no need for firearms, but sadly this will never be. Until then, it will take a majority of Americans to amend the Second Amendment, and it's not happening in our lifetime.

Anyway, 73 to you and Dwight and everyone else taking part in this gun-free exchange. I'm QRT.

The FCC does not own any spectrum, but they are more or less a combination of the Wall Street and
Judge Judy when it comes to spectrum assignment. The Wall Street part of them would like to auction off every Hz to the highest bidder, and the Judge Judy in them would like to make everybody happy while collecting a large salary. Since this is irreconcilable, we have a problem,
and that problem is an increased pressure on our bands. Now, the real owner of the bands is actually everyone and no one, which means that regular Joe Sixpacks eventually may get to determine the fate of amateur radio (indirectly, of course - whoever heard of Joe Sixpacks running the country; that's what we have politicians for). As a matter of fact, "our" bands are
not at all ours, since we have already stated that everyone owns the spectrum, and the ham-radio
population happens to be a very small percentage of the US (and world) population, which means
that Joe Sixpacks don't give a rat's behind about us and our perceived needs. Therefore, if there
is no strong, organized and unified effort of the entire ham-radio population, the spectrum will
start to disappear no matter how many no-code licenses are given out and no matter how many VHF
radios are sold. By far the best vehicle for such an effort is always a national ham-radio organization, which in the US happens to be the ARRL. That is why it is my belief that every US
radio-amateur should support the ARRL in one way or another, even if he/she differs

philosophically with it in some or most other issues.
I haven't even begun to address the problem of the international scope: the HF spectrum demands
of the developing countries. The WARC and ITU will not so much as glance at petitions coming from
any sources other than recognized national ham-radio organizations. The FCC can only go so far
within the limits of the international agreements, so the real battleground is actually outside
of the US soil.

And now I rest my case.

73 ..... Zoran

Source record: 167159

Roy et al:

I believe that everyone here on the thread now agrees...

The Antenna Book article and statement are misleading!

As to Wattmeters, SWR meters, Forward, Incident, Reflected, Transmitted and Delivered Power and such...

Waves are completely arbitrary!

As they say, beauty is in the eye of the beholder, and the reality of waves is just a function of your viewpoint (aka bridge reference impedance).

Everyone seems to agree that it's clear that you can get any answers you want among these "wave units" just by varying the basis of your metrology... it all depends upon the reference impedance (Zo) used as the normalizing basis for measuring the "waves".

I once asked on our newsgroup if any manufacturer makes directional couplers (and/or directional wattmeters) with a variable reference impedance. No one answered my query.

We should recall that a directional coupler is nothing more nor less than an elementary bridge circuit, the unknown impedance is simply compared to a known (reference) impedance connected to the "bridge" arms by measuring the difference (voltage or current) across another bridge arm. If the unknown impedance equals the reference impedance, then the bridge is balanced and the reflected wave is zero! Nothing mysterious there. Change the known impedance and the difference reading changes! Everything on the line is the same. You can make the meter read whatever you want!

The so-called "reflected wave" is nothing more nor less than an artifice created in the bridge by the comparison to the reference impedance. Change the meter's reference impedance and you change the measured wave! It's completely arbitrary. As they say at Burger King, you can have it your way!

As near as I can tell, ALL of ham related directional couplers/wattmeters that you can buy from Ham Radio jobbers use 50 Ohms resistive as the reference impedance. So my point is moot. Most hams BELIEVE that all wave mechanics is measured against 50 Ohms. They simply have no choice, the meter manufacturers give them no equipment to do otherwise.

In principle one could build or manufacture directional wattmeters with any arbitrary reference impedance. I would like to be able to buy one with a programmable reference impedance. It's just that the transmission line work done by hams is very simple compared to the general case since it is assumed that all ham transmission lines of interest have exactly 50 Ohms resistive

surge impedance. What?

In my professional work we had, and still have, reason to construct directional couplers that use (extremely) complex high order reference impedances. Why? Because the impedance of our transmission lines varies all over the map, by as much as several orders of magnitude within our band of interest! It's a very wide band.

The surge impedance on our wideband transmission lines in the lower part of the band is several thousand ohms and highly capacitive, and in another part of the band the surge impedance is less than 100 Ohms and very lossy. And the surge impedance varies all over the map in between the band ends. Crazy but true!

Attempting to "separate" the incident and reflected waves on those lines is a problem that opens your eyes to the reality of forward and reflected waves and the over-simplicity of much of the associated metrology!

But we do it every day on millions of lines. There are probably about 150 million such lines and transmitter receivers in use daily. And forward and reflected "waves" are being separated on those lines daily by directional couplers using extremely high complexity reference impedances. Certainly not 50 Ohms!

Even in my ham work, I don't know the characteristic impedance of my "home made" transmission lines, don't know and don't care. They are lossless lines for all practical purposes, but have characteristic or surge impedances far.. far... away from 50 Ohm's resistive. The only reason I use a 50 Ohm resitive reference directional wattmeter, is because the manufacturer of my transmitters designed the PA's to "like" 50 Ohms. Has nothing whatsoever to do with my antennas and transmission lines...

My ham radio directional wattmeter is just a 50 Ohm bridge that I use to assist me to adjust my arbitrary unknown impedance so that my transmitter PA's are "happy".

Who knows or cares about the direction of those "arbitrary" waves on my lines.

Roy:

Yes transresitance, and transconductance for that matter, seems to have the folks at the "Church of Dissipationless Resistance" mystified.

Then there is that other resistance. You know... The ratio of the voltage across the power entrance panel at the Brackett home divided by the current flowing into the power entrance panel of the Lewallen home. Now that particular ratio has units of Ohms and is then certainly a resistance.

I wonder if it can be classed as dissipationless?

Now that the members of the "Church of Dissipationless Resistance" seem to have "legitimized" dissipationless resistance, I wonder if we can sell it to those poor folks out there in California, so that they can heat and light their homes using the wonderful dissipationless effect.

Dissipationless Resistance should be proposed to Gray Davis and the California legislature as the "cure" for the Golden State's power shortage problems.

Dissipationless Resistance indeed!

I don't agree that waves are arbitrary. If you apply a signal to a transmission line of a known impedance and velocity factor and terminate it with a known impedance, you can say with certainty what the value (both voltage and current) of forward and reflected waves are on the line, how they interfere with each other, what the SWR (i.e., ratio of maximum to minimum voltage along the line) is, what the impedance is looking into any point along the line, what the voltage and current -- both magnitude and phase -- are at any point along the line, how much power is flowing in the line, and, if you like, you can separate the power into "forward" and "reverse" components with known values. The values of these quantities do not vary with measurement method, but are determined solely by the characteristic impedance and velocity factor of the line (or more concisely by its complex propagation constant), the load impedance, and the applied voltage, current, or power. You can find the simple equations to do this in numerous references. My favorite is Reference Data For Radio Engineers.

What happens, though, is that some people, particularly amateurs, do careless measurements or misinterpret the measurements they're making. For example, a person connects a transmitter to a 75 ohm line through a 50 ohm SWR meter and mistakenly thinks that the meter reading is the SWR on the line. It isn't. Likewise a directional power meter. Certainly, you can reach all sorts of bizarre and incorrect conclusions by claiming that you're measuring something that you're not. But waves are real, well defined, and readily calculable, and don't depend at all on how they're measured.

> what kind of "sticks" do you mount them on?

I turn helical wound "hamsticks" etc into "plastic bugcatchers". On my
all band version, the coil is only used for 80/40 meters. There is one
tap for 40m. Small changes can be had by adjusting the stinger. The
stick in this case is an old firestick cb antenna I got free. It's 5 ft
tall and the coil is halfway up it. For 80/40m ,I use about a 4 ft
stinger on top of that. About 9 ft total. 20-10m are tuned by bypassing
the coil with a jumper and using a different stinger for each band. This
antenna properly works all bands 80-10 including warc.
But you have to get out and change it. But takes me 2 min. My usual
practice is 40m in the day. When traveling I'll hit a gas station on the
interstate when it gets dark, and change over to 80m while the car is
filling up. I think I'm going to try 160m mobile next winter. Little
late this winter for the noise, and I need to get a small solid state
amp to run. Also will have to scheme up a new antenna or coil add on for
that band.
I would have done it by now, except my old radio didn't have 160m, so I
never got to try it. My new one does, so I will have to check it out.
I'm a glutton for punishment. 160 mobile will be a real challenge. But
it does work. I've talked to many of them. Most all run a bit of juice
though. 500w would be just dandy. MK

We also don't know how *much* each field changed.

I asked if the signal on the loopstick also decreased a large amount.
I'll wager it did.

Wth that in mind, what is the relative sensitivity? Does the radio
disconnect the loopstick when using the rod, and vice versa? Virtually
all don't. If so, how do you know what the response is.

The point I was going to make is the meter does not really measure SWR
or forward and reflected power. It is calibrated to read those things,
but it really looks at one slice of the line and "has no idea" what is
happening with standing waves.

Now if you moved a detector along the line, you could see the standing
waves. It would not have to be calibrated to the line, it would only
have to indicate the ratios of the parameter it reads (voltage or
current) accurately.

Traditional meters are circuit systems, not transmission line systems
where waves stand. They are set to null on a certain ratio of in-phase
voltage and current. They can very easily give the wrong answer if
they are not used in a line that is the same Zo they were calibrated
to be used in.

Predicting what the meter will read is dangerous, unless you know what
the meter actually measures. It doesn't mean there are no standing
waves, just because someone is giving the meter credit for doing
something it can not do Peter.

No, not at all. A tuner can work three ways:

It can cancel either the parallel or series reactance, and leave the
real part of the impedance.

It can act like a resonant transformer.

It can act like a transmission line of variable Zo and electrical
length.

>When the feedline impedance equals that
>of the antenna, the antenna is supposedly purely resistive and it becomes an
>electrical load, which feedline capacitive reactance should be near zero.

Purely resistive means the reactance is zero, both inductive and
capacitive.

>1. If one were to install a transmatch in feedline system that already has
>an antenna that is purely resistive (1:1 match) what would be the insertion
>loss in dB resulting from the insertion of this device? Ive never really
>thought about it until recently.

Depends on the tuner and how you adjust it, as well as the load
impedance. Most tuners are pretty efficient, because virtually all of
the loss is concentrated in the inductor. Even a small amount of loss
really shows up at high power, because even a few percent loss exceeds
the dissipation limit of most components.

>2. What is/Is there a linear relationship of insertion loss resulting from
>the transmatch installation in relation to the inductive reactance present
>at the transmitter? i.e.. At what point are you better off having the radio
>fold back somewhat as compared to the insertion loss incurred by the
>installing a of transmatch?

First, your perception of how the tuner works is incorrect. Any answer
would either be very very long, or might confuse you.

You might get a copy of the book "Reflections" by Walt Maxwell and
read it.

To answer your question simply, the best condition for the tuner is adjusted for a 1:1 SWR at the radio. This assumes your radio was designed correctly.

The proper way to adjust a "T" network tuner is for the lowest SWR while having one or both capacitors at the maximum possible capacitance that allows a match. Efficiency in the tuner gets gradually and slightly worse as you open the capacitors more than is necessary, and power handling drops off quite a bit because voltages get high.

There are a lot of myths, misunderstandings, and folklore about tuners. That's 90% of the problem, rather than the tuners themselves.

Gary,

Please share with us how you determined the efficiency of your system.

Most of your numbers are totally unrealistic, in particular 160 meters
and 80 meters.

So tell us, how did you determine the efficiency?

The part of the line's characteristic impedance that doesn't dissipate
any power is dissipationless, by definition.

> When a cable has loss, not all the power is dissipated in the load. Some
> is dissipated in the cable.

The example was for a lossless cable. Whatever part of Z0 exists that
doesn't dissipate any power, it doesn't dissipate any power. The same
power cannot be dissipated in two separate places.

> It's the voltage at the output of an amplifier divided by the current at

>and 10, and I even get a 3:1 swr on 30 and 12 meters.

Despite all the folklore and how the antenna was originally intended,
the normal G5RV works fairly well as a three band antenna (and is
quite usable on other bands with a tuner). The typical G5RV has a
modest SWR at the low end of 80, the high end of 40, and 20 meters.

If yours was exactly half size, it should have a moderate SWR on 10
meters, 20 meters, and 40 meters.

That seems to be what you are having, and so everything looks OK.

Efficiency will be good on those three bands. Virtually all of the
losses are feedline losses, and the feedline you have is short. Also
the SWR is fairly low on at least three bands.

Don't expect a low SWR on other bands, it probably won't happen
without a tuner in line.

Rudy,
I have a X7 up and will change the whimpy cushcraft balun when I rework and check the X7 in a couple of months. I will be putting a Centaur 4:1 balun on the antenna.
http://www.baluns.com/b41y.htm

I'm using this 4:1 balun currently on an 80 meter antenna at the bottom of 40 feet of ladder line with coax into a tuner. Works gud on all bands..

Hi Rich,

Although 160 would benefit from lengths longer than 400 and less than about 900 feet, a 400 foot long Beverage, if properly installed, would be a reasonably good 160 meter receiving antenna for most applications.

At 400 feet, the antenna would be failry directive. It might hurt the reception if it is not "aimed" at the desired direction. It would be quite directional on 80 and higher, of course.

The best antenna is always the most directional one that fits your needs, and no one can answer that question without knowing a lot more information than you gave.

What direction(s) do you want to receive? What distances? What is the source of your noise, is it power lines and stuff nearby or distant noises?

How much clear area away from power lines, antennas, and other large conductors do you have?

I'm afraid you will just get random off-the-cuff answers unless all of that is known.

The designer of the SWR meter. If the design assumptions are meet,
the SWR meter works fine. Any instrument can be misused.

Any directional wattmeter with a calibration adjustment has a variable
reference impedance. Assuming the current pickup coil is fixed, if you
design the voltage pickoff capacitive divider with enough range, the
reference impedance can be varied over a wide range and could even have
a selectable calibration knob on the front panel.

One fact that is a bit of an eye-opener for some people is that the
modulation on the waves can be located exactly where and when it
should be according to wave theory. Modulation can be used to identify
the individual waves in space-time.

> But waves are real,
> well defined, and readily calculable, and don't depend at all on how
> they're measured.

Like I said in another posting, the designer of the SWR meter assumes
something about the characteristics of the waves. In particular, he
assumes the forward voltage divided by the forward current is equal
to the reference impedance of the SWR meter.

>size dipole or a magnetic loop ant for 20 mtrs?

There is no magic to any antenna.

Radio waves are electromagnetic, NOT magnetic. You can not have a
time-varying electric field without a magnetic field, and vice versa.

I assume you are talking about real "magnetic" loops and not
confusing large loops with "magnetic" loops. "Magnetic" loops, by
definition, are very small. They are generally less than 1/10th
wavelength or so in circumference.

"Magnetic loops", just a few feet from the antenna on 20 meters,
actually have a stronger electric field than magnetic field. But very
quickly, as distance is increased, it becomes exactly the same as the
field from a dipole or any other antenna. It is only right next to the
antenna that they are magnetic dominant, and they STILL have an
electric field.

"Magnetic loops", contrary to myth and rumor, are no better than any
other antenna for transmitting. As a matter of fact, they are
generally worse. While a full-size dipole is nearly 100% efficient, a
magnetic loop would be hard pressed to make even 30% efficiency.

The real advantage of magnetic loops are the small size, and wide
tuning range. Changing a single component (a capacitor) will allow a
single antenna to operate over a wide frequency range...perhaps 30
through ten meters or 40 through 15 meters.

The bandwidth for each setting will be narrow however, so you have to
watch the capacitor setting carefully.

By all means, if you have the room, use a dipole!

It's hard to beat the efficiency of a 1/2WL dipole at a height
of 1/2WL+. A lot of power can be lost in the necessary matching
circuitry for a small loop and in the loop itself.

Thank God! You had better hope and pray that those in power are never able to convene a Constitutional Convention again. With the current beliefs and attitudes of many in Congress these days the Second Amendment is not the only thing that would be at risk. The First Amendment would be right behind it, and then the Fourth, etc.

A Constitutional Convention is the single most dangerous thing that the current crop of politicians could do. The aftermath would be the end of the United States as we know it...

Tom, W8JI wrote:
"The time-varying fields can NOT pass through a conductor several skin depths thick."

Tom is saying the magnetic component of an electromagnetic wave cannot penetrate the concentric shield over a loop antenna. That misconception must be at the bottom of his claim that the electrostatic Faraday shield becomes the antenna.

Tom is dead wrong. The shield is broken with an insulator in the middle which has no current path shunting the insulator. The shield can`t have significant current flow, so no effective opposing counter-field is generated, ala Lenz.
This makes the shield as porous as a sieve for the magnetic field, and the external r-f field passes right through the metal external shield. The shield remains impervious for the electric field.

The above action is how the Faradauy shield works.

Best regards, Richard Harrison, KB5WZI

Tom, W8JI wrote:
"If you short the gap (of the loop shield), you force the voltage to zero and the loop goes dead."

That seems to be another example of Tom`s misconception of how a Faraday shield works. It is not destruction of transformer action that kills the signal.

Of course you kill a loop antenna when you short the gap in the shield. Lenz`s law comes down on you. The external r-f field can now generate a counter field which, when added to the inciting field, add to nearly zero at the surface of the shield. That is how the shield on coax works to keep signals in and out. Break the shield, and magnetic coupling can occur, and the shield is no longer effective for the magnetic component of the EM wave.

Best regards, Richard Harrison, KB5WZI

Tom, W8JI wrote:
"Noise is a signal just like any other signal."

I would say that noise behaves just as a signal does and follows the same propagation rules.

Close to the source of either signals or noise, the electric field is significantly a larger part of the EM field, so if we can sieve it out of the combined field, the magnetic field passed on to the antenna near that noise source produces a better signal to noise ratio. The Faraday shield does just that.

Best regards, Richard Harrison, KB5WZI

6322. Use velocity factor for folded dipole?

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-30 14:39:15 UTC
From: Rick Matthews <matthews@wfu.edu>
Message-ID: <3AC49A93.71DED4AA@wfu.edu>
Source record: 167096

When designing a folded dipole made from twinlead, should one use the velocity factor of the twinlead in calculating the length?

I would have assumed so, but the various web pages I have found with antenna length formulae seem to have the length pretty close to a half wavelength in free space, not the 17% or so less I would have expected.

What am I missing?

It is if the forward voltages in both meters are the same. That is why I
qualified my statement with that assumption.

I would agree that my assumption is incorrect in the example that you
describe.

You make these statements like something out of the ordinary is happening or
that models can't predict this real world behavior.

In the 450 ohm line terminated with 450 ohms there are no standing waves. A
450 ohm meter will read forward power and zero reflected power.

Insert a 50-ohm wattmeter into a 450 ohm line and what happens? You just
created an impedance discontinuity in the 450 ohm line.

The output side of the 50 ohm wattmeter sees a 450 ohm steady state line
impedance: It sees a 9:1 SWR. As a result of this 9:1 SWR, there is now a

standing wave in the 50 ohm wattmeter. By inserting the 50-ohm wattmeter you created the reflection that it indicates. The reflection it indicates is very real.

The 50 ohm wattmeter indicates a higher forward power as a result of the re-reflections created at its input. Looking rearward it sees a 450 ohm impedance discontinuity.

In the 450 ohm line in front of the 50 ohm wattmeter, the SWR will go up only slightly (1.1:1) because the line length in the 50-ohm wattmeter is very short and it does not transform the 450 ohm steady state line impedance very much. So, a 450 ohm wattmeter will not read very much reflected power. It will not read "zero" reflected power.

>

I am not sure why you have a problem with theory or models. They work quite well to explain the situation you are describing. The real world does not behave differently than the models predict, even with a 50 ohm wattmeter in a 450 ohm line.

The 50-ohm wattmeter will indicate zero reflected power every 1/2 wavelength from the termination because it sees a 50 ohm steady state line impedance at that point. Move it slightly and the impedance it sees is no longer 50 ohms. It now indicates a reflection.

Only when the 450 line is not terminated in 450 ohms.

When you move the 50-ohm wattmeter along the line, the steady state line impedance it sees varies. That's why the SWR varies. Everything that happens here is consistent with transmission line theory.

I am not sure of your point here. The relationships I stated above are
correct.

A wattmeter, will indicate a forward and reflected power. The power
delivered is equal to Pforward - Preflected.

If the meter is not normalized to Zo, it will not indicate the same forward
and reflected power as a Zo wattmeter. The power that the non-Zo wattmeter
indicates is correct for its Zo design.

Tom, W8JI wrote:
"Faraday shields, for RF applications, are strictly common-mode devices...."

No, a Faraday shield can`t usually be called just a common-mode device. The Faraday shield in nearly every mediumwave broadcast station in the world is a grounded shield between unbalanced coils (one end of each coil is grounded). Where is any common-mode there?

For a common-mode, there has to be at least a pair of something, or you`ve nothing to have something in common with. You have to have a balanced pair of wires, inputs to a balanced amplifier, or something besides an unbalanced feed.

Anyway, this is just another diversion from the straight-skinny on how the Faraday shield on a loop antenna works.

Nope, the specified velocity factor of a transmission line is
referenced to differential currents. The currents in the antenna
portion of a folded dipole are common-mode and the common-mode
velocity factor is pretty high, maybe around 0.95.

Typical built in tuner in modern rigs loses about 20% of power.
Easy to verify, load the rig to dummy load, put external wattmeter between the rig and the dummy and switch your tuner in and out, you will see about 20 % drop, like instead of 100W you will get 80 watts.
I value my watts and always try to design antennas that have 50 ohm feedpoint.

Roy, W7EL wrote:
"But, I`m still confused about that amplifier transresistance."

It has to be the inverse of transconductance.

You put something in over here and it affects something over there. This is like mutual impedance where a voltage across a pair of terminals over here causes current in a circuit over there.

In these "trans" and "mutual" things there are intervening variables depending on how close the relationship really is. That`s why I proposed the term "ringer resistance" as a generic type resistance which would include "transresistance". A ringer is a likeness, but not the real thing.

Thank you all for the very informative feedback on this.It seems that Tom, W8JI's answer is the short and sweet one - the half-size G5RV is good for 40, 20, and 10. I can live with this, it was just that the ARRL handbook's brief description lead me to believe that it truely was an all-band design. But even the fact that it works on 40, 20, and 10 without any other tuning apparatus is quite remarkable. So, I guess it's back up into the trees to string an additional 15 meter dipole.

Thanks again for all the info and 73's,

That's true, it is, but, in network theory, transresistance is
convenient for describing the behavior of a current-controlled voltage
source. Your house and Roy's house don't constitute a
current-controlled voltage source do they Cecil?

> must be at the bottom of his claim that the electrostatic Faraday shield
> becomes the antenna.

The statement that time-vaying fields can NOT pass through a conductor
several skin depths thick is correct.

If a time varying magnetic field did exist inside a good conductor than
it would be necessary for a time varying electric field to
simultaneously circulate in a perpendicular direction. Ohms law states
that the existence of such an electric field would also require
conduction currents to flow in the conductor. In the case of a good, but
not perfect, conductor, the conduction currents will lag (in time)
behind the originally postulated magnetic field. The magnetic field
associated with the conduction current will be in a direction which
opposes changes in the original field but will lag in time and not
result in complete cancellation of the original field until a depth of
several skin depths is reached.

> Tom is dead wrong.

I think nearly everyone posting to this thread is attempting to over
simplify the physics involved. Electric and magnetic fields are
vector fields, that means they have both magnitude and direction. The
laws of electromagnetics, including Ohms law, require treating both the
electric and magnetic fields as vectors at all times. It is common
practice in special cases such as transmission lines where the electric
field can be assumed transverse to the direction of propagation and the
conduction current longitudinal, to drop the vector notation since the
fields can be completely determined from the voltage, current and
transmission line physical characteristics.

The concept of 'field impedance' has some value when considering a
propagating wave where the electric and magnetic fields are mutually
perpendicular, and normal to the direction of propagation. In general,
the operation of dividing one vector by another is not defined.
Therefore dividing the electric field by the magnetic field has no
meaning unless other information is also somehow specified. Dividing the
magnitude of E by the magnitude of H gives the relative proportion of

energy stored in the electric and magnetic fields but provides no
insight into where the stored energy might be moving.

> The shield is broken with an insulator in the middle
> which has no current path shunting the insulator. The shield can`t have
> significant current flow, so no effective opposing counter-field is
> generated, ala Lenz.

Correct, assuming the antenna is orientated for maximum response to an
incident electromagnetic wave. Note that a correctly polarized wave
arriving broadside to the direction of maximum response _will_ induce a
current into the shield which will couple to the pickup loop. Usually
this results in increased response to high angle horizontally polarized
waves arriving broadside and is one of the reasons loops are marginal
direction finding antennas at HF.

> This makes the shield as porous as a sieve for the magnetic field, and
> the external r-f field passes right through the metal external shield.

What evidence do you have the magnetic field penetrates the shield? What
observable behavior of the system suggests the magnetic field penetrates
the outer shield? Tom's point is that the voltage induced in the pickup
loop (per turn) is identical to the voltage induced in the shield. If
Tom is correct, then negligible magnetic field from the oncoming wave
penetrates the shield. Can you devise a practical experiment which
could disprove Tom's assertion?

Hi Cecil,

Why "wouldn't?" Or why "couldn't?".

As negative resistance (a real example found in some semiconductors)
presents a step discontinuity to an increase in voltage, it would make
a very problematic Thevenin source. It would also have a tendency to
oscillate depending on the load.

You sure Enron hasn't already got this patented for power contracts to
California?

6341. Re: A question about Transmatches - Please wiegh in!

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-30 17:22:16 UTC
From: Paul <pvanasse@mail.direcpc.com>
Message-ID: <qi3x6.36201$m8.300646@news.direcpc.com>
Source record: 167113

: I think you have the theory all wrong about the transmatch. Anyway without
getting into the theory

How so? The transmatch is essencially a variable capacitor that when
inserted into a perfectly matched feed system will produce (vary) inductive
reactance on the transmitter side and insert capacitive reactance (unless
tuned) on the antenna side to zero, regardless of of where the transmatch is
located in the feed line. Are you saying that no inductive reactance is
present? Please explain your theory.

: can loose about 5 to
: 10 percent of the power if it is working as it should and more if it is
: not. My MFJ looses about 10 watts out of 100 going into it on 80 meters
: when fed into a good dummy load and less as I move toward the higher
: frequencies. The mfj is not the greatest but typical of the inexpensive
: ones.

Where did these numbers come from? Are these the stated numbers that come
with the specs of the transmatch or are these practical numbers observed at
your station?

Using the MFJ numbers you stated the total insertion loss resulting from the
transmatch installation would be:

dB = 10 log (.9) = .45 dB insertion loss.

If one adds this loss number to the losses incurred by running100' of
RG-213/U at 3.5 Mhz (.4 dB), the total loss over the entire feedline would
be .85 dB.

This equates to:

.85 dB loss / 10 Inverse Log = 1.22 Power Loss Factor

100 Watts / 1.22 Power Loss Factor = 81.97 watts seen at the antenna feed
point or a 18% overall loss using the transmatch.

Now lets say the same 100 watt radio is folding back 10% due to a slight
mismatch and one decides to NOT use a transmatch, however they still use the
and the same RG-213/U cable at 3.5 Mhz.

.4 dB loss / 10 Inverse Log = 1.1 Power Loss Factor

90 watts / 1.1 Power Loss Factor = 81.82 watts seen at the antenna feed
point or 8.2% overall loss using no transmatch.

The numbers are practically identical. Granted, the radio will be working
alittle harder converting energy into heat but I dont think that a 10% or

even a 20% foldback ever really hurt a transmitter. On the flipside, the Law of Reciprocity states that this ficticious transmitter (the one without the transmatch) would loose 10% of its receive capabilities, but how serious is 10% with the noise floor of modern tranceivers?

:
: For question number 2, The loss is in the feed line from the transmatch
: to the antenna. Unless you plan on putting the transmatch at the
: antenna you will have the same losses in the feedline if you do or do
: not use the transmatch not counting the 5 to 10 % loss in the
: transmatch. YOu do not want the transmitter to fold back as it is not
: operating efficently and will put stress on the transmiter circuits and
: possiably shorten the life of the transmitter. YOu use the transmatch
: to mask the swr so the transmitter will operate with more efficency.

See above.

Thanks for the response and 73

>Best regards, Richard Harrison, KB5WZI

You seem to be stuttering with multiple posts saying I am wrong Richard, instead of addressing the question. You also are arguing against yourself.

Clearly a time-varying magnetic field can not pass through a conductor several skin depths think, and clearly (you agree to this in a later stutter-post) the loop acts like a transformer between the secondary (the inside winding) and the primary (the outside shield). When you resonante the rpimary, mutual coupling resonates the seconday. If you resonate the secondy, mutual coupling will resonate the primary.

That transformer action is how the "shielded" loop transfers energy from the shield to the center. The shield, resonanted through mutual coupling to the resonant secondary inside, becomes the antenna. The field impedance of that antenna is very little different than the secondary winding alone would be without the shield.

The only major difference is the amount of reactance to resonante the loop can change, and the balance can change. If you do NOT ground the shield in the electrical center of the shield it can actually hurt the system balance, and increase response to undesired electric fields.

The shield has a very high impedance across the gap in a loop that is resonant, and the impedance is no different than if the tuning capacitor was moved across the gap and re-adjusted to resonance at the new location.

There really isn't anything magic about all of this, it's pretty basic stuff. You can't have the loop violate the same "laws" and principles you are attempting to use to support your claims the shield is NOT the antenna in a shielded loop.

Why not take a deep breath, and read what Bart wrote if you don't like my way of explaining it?

No, there is no discontinuity at all over what the normal sampling of
a meter for another Zo would cause.

I am only trying to point out HOW the meters we normally use
work,since that seems to be what is tripping you up a bit in some of
your comments. I'm not disagreeing with your transmission line
analysis, just with what you say a meter will indicate.

>The output side of the 50 ohm wattmeter sees a 450 ohm steady state line

>standing wave in the 50 ohm wattmeter. By inserting the 50-ohm wattmeter
>you created the reflection that it indicates. The reflection it indicates
>is very real.

A well-designed meter looks like nothing at all to the line. The Zo
setting of the meter has nothing to do with reflections on the line.

>The 50 ohm wattmeter indicates a higher forward power as a result of the
>re-reflections created at its input. Looking rearward it sees a 450 ohm
>impedance discontinuity.

No, it does not. It indicates a higher power because the voltage
divider has more voltage. It is a simple circuit that sums voltages
provided by current through the line and voltages across the line.

>In the 450 ohm line in front of the 50 ohm wattmeter, the SWR will go up
>only slightly (1.1:1) because the line length in the 50-ohm wattmeter is

>It will not read "zero" reflected power.

It will not read zero reflected power because the ratio of voltage
provided by the current sample is changed when compared to violtage
across the line.

>I value my watts and always try to design antennas that have 50 ohm feedpoint.

Yuri, I just checked my FT1000D. The worse band is 160 meters, as it
is with most T network tuners.

On 160 meters with no tuner, the power to the load is 200 watts. With
the tuner, the power to the load is 187 watts. That's 93.5% of the
power delivered, or .29 dB loss.

On 40 meters output power with no tuner is 182 watts. With the
internal tuner it is 179 watts. That's 98% efficient, and only .07dB
loss.

Very few tuners lose 20% of the power, even on 160, unless the load
impedance is very low.

Can you tell me where you numbers come from?

>of its responding to something other than the vertically polarized
>electric filed I have shunted.

You cannot eliminate the electric field in a region and leave an oscillating
magnetic field. It violates Maxwell's equations. If you have
Curl E = -dB/dt, you cannot have a nonzero right hand side and a zero
left hand side. If E=0 throughout a finite region, the left side is zero,
and an oscillating B field is not possible.

>The experiment of placing an entire (small) radio with electric probe
>antenna inside a conducting tube shows that the electric field does not
>much enter the tube; placing a loopstick-equipped radio inside shows
>that a signal can still be received. This is indicative that the
>grounded roof example is carried over in the example of conducting
>tube.

I am not sure if I understand your experiment, but assuming your
conducting tube was thick enough, you basically have a waveguide below
cutoff. You could test this by making the tube longer. The signal
detected should drop exponentially with length with the usual wave
guide far below cutoff result:
Attenuation = 40*pi/ln(10) (l/lambda_c)
where l is the length and lambda_c is the cutoff wavelength of the
relevant mode, ln(10) is the natural logarithm of 10 about 2.3026. The
lowest mode has a cutoff wavelength of about 1.7 times the diameter.
Therefore for a 7 inch diameter and 15 inches to the middle, I expect
an attenuation of around 10 dB for the lowest mode. Higher modes will
have a few dB more attenuation. So if you could make the 30 inch pipe
twice as long, your signal would drop by about 10 dB assuming the pipe
is many skin depths thick. This would demonstrate that the signal is
not coming through the metal, but rather in through the ends of the
pipe. Once the pipe is long enough, the lowest waveguide mode will
dominate, and you can look up the field patterns in many places and see

how to orient various antennas to maximize coupling.

>I don't argue that electrons are accelerated by an electric field. But
>it isn't impossible that they can be accelerated by a magnetic field,
>for permanent magnet generators would not work unless they could be.

Yes, I gave the Lorentz force equation which tells how the magnetic field produces forces on charges.

The electrons in a region of copper in your antenna are initially at rest (assuming that we are talking about a stationary antenna). In a permanent magnet generator, either the magnet is spinning in which case there is an electric field that drives the electrons, or the copper wire is moving through the magnetic field. In that case the electrons aren't initially at rest but have a net velocity (the velocity of the wire) and they certainly respond to the magnetic field. However, I assumed we were talking about stationary antennas. Even in the case of moving wires, in the rest frame of the wire it is the electric field that is doing the work. There is no way to have a force on a charge at rest from a magnetic field if you accept the Lorentz Force equation. The work done on the electrons in a loop antenna is done by the electric field.

>Given that there are always orthogonal counterparts to the electric or
>a magnetic component of the electromagnetic field, then there has to be
>an electric field inside the shield, associated with electrons
>accelerated by the magnetic component of an incident electromagnetic
>field. But it's a different electric field than exists outside, as is
>demonstrated by the fact that electrons are made to flow in the loop
>conductor even when we shunt the external electric field.

If you have been arguing that there is an electric field everywhere but sometimes it is a "different" electric field, then, since I have no idea what measurement to make to tell which fields are the "same" and which are "different", I will stop commenting. If you are saying that you always have an electric field in a finite region when you have an oscillating magnetic field then that is what others have been saying too. Since the electric field goes to zero exponentially in a distance of a few skin depths, both the magnetic field and the electric field deep in the shield go to zero if it is many skin depths thick. The field energy then gets from outside the shield to inside or from one side to the other by going through the gaps. That is what Tom, Roy and others have been saying, and possibly you agree too.

Inserting a short section of 50 ohm line into a 450 ohm line causes an
impedance discontinuity. It may not make much difference in what you see in
the 450 ohm line before the discontinuity but it has everything to do with
what you see in the short section of 50 ohm line.

Take the plug out of a bird wattmeter and look at the 50 ohm line. This 50
ohm line behaves no differently than a 3 inch air dielectric transmission
line. There will be a rearward traveling wave on this line. That's why the
50 ohm wattmeter indicates reflected power.

Yes it does. Transmission theory and the behavior of traveling waves does
not change because the line is short.

The voltage divider has more voltage because of the impedance
discontinuities created by the 450 / 50 / 450 ohm mismatch.

> any power is dissipationless, by definition.

That's fine, but does the characteristic impedance dissipate any power? If not, I assume that the characteristic impedance of all cables, regardless how lossy, is "dissipationless". So If I have a very long and lossy cable, I can lose all my power in a line with "dissipationsless" Z0?

No, the question is about a cable with loss. A lossless cable is a trivial case that even I can figure out.

> > It's the voltage at the output of an amplifier divided by the current at
> > the input.
>
> The voltage at your house times the current at my house is meaningless.

Indeed. But the voltage out of an amplifier divided by the current in is valid and useful. "Norton" amplifiers, which have a low impedance input and whose output is determined primarily by the input current, often are specified this way. Transresistance is a useful parameter. But if it bothers you, let's talk about transconductance instead, since it's probably more familiar. This is the output current divided by the input voltage, and is often used as a specification for tubes and FETs. Since we have dissipationless resistance, we surely must also have dissipationless conductance, no? So is a tube or FET transconductance dissipative, dissipationless, or some of each? If some of each, how much?

No, the transresistance of an amplifier (output voltage divided by the input current) is the reciprocal of its transconductance (output current divided by the input voltage) only if the voltage gain is the reciprocal of the current gain.

Wow, I'm getting richer every day. Just a short time ago, all I had to work with was resistance. Now I have "dissipative", "dissipationless" and "ringer" resistances. They just seem to keep popping out of the woodwork. How many more kinds are there? I've learned that resistor leads act as a type converter, converting between "dissipative" and "dissipationless" resistances. Are there converters to convert "ringer" resistance to the other kinds?

Cecil, do you agree with this? That is, is there a third pigeon hole where we can put the pesky resistances that aren't obviously "dissipative" or "dissipationless"?

> present? Please explain your theory.

The transmatch usually matches the R +/- jX at the input of a transmission line to the 50+j0 required by the transmitter. The antenna reactance can be either inductive or capacitive or zero. The antenna resistance can be low, medium, or high. The meaning of your statement above is unclear. The transmatch is not a variable capacitor. The transmatch is a matching network containing (typically) one variable inductance and two variable capacitors.

A pi-net tuner will have lower losses than that into a 50 ohm dummy load.

I design antenna systems that have a 50 ohm feedpoint at the transmitter
end of the transmission line. For instance, a one-wavelength dipole has
gain over a 1/2WL dipole. If the feedpoint impedance is 4050 ohms, 1/4WL
of 450 ohm ladder-line will result in a perfect match for a 50 ohm
transmitter.

If a resistance isn't dissipating power then it is obviously dissipationless.
One cannot make a silk purse out of a sow's ear. :-)

Seriously, let's say we have a one-wavelength dipole with a feedpoint
impedance of 4050 ohms. We feed it with 1/4WL of 450 ohm ladder-line.
We measure a resistance of 50 ohms at the input to the transmission
line. That 50 ohm resistance is dissipationless.

The part of Z0 due to the distributed L and C is dissipationless.
I'm not sure about the other part. I generally conceptualize
only about lossless lines.

> So is a tube or FET transconductance
> dissipative, dissipationless, or some of each?

Does V*I*cos(theta) have any meaning at all when dealing with
transconductance. I don't see that it does. After all, if a
voltage and current are not together, they cannot produce any
power. I would say the ability of transconductance to dissipate
power is undefined.

Richard Clark wrote:
"Actually, I`ve often wondered - why wouldn`t a power source be a
negative resistance?"

To the phone company, a power source is often a negative resistance.
Phone companies amplify traffic on their lines with "negative resistance
repeaters". All that can be done on a 2-wire circuit is offset circuit
loss, else it will "sing".
Signal processing could change all that. I`m referring to ancient
technology. Digitally, time slots could be assigned to transmission
directions to keep the signals separate on the same pair of wires. That
is done with analog multiplex carrier, but you seldom have a 4-wire
phone set. With a codec in the phone set? Why not all the gain you want
in both directions, anytime?

The answer to your question is no. The feedpoint impedance will be
very high and variable on most bands. The only way you can get the
wire feedpoint impedance transformed to 50 ohms resitive is with a
wide-range tuner like several of the MFJs. You'll also need a good
ground and/or a counterpoise to complete the circuit.

6364. Aluminum Tubing

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-30 19:55:55 UTC
From: W6RCecilA <Cecil.A.Moore@IEEE.org>
Message-ID: <3AC4E4CB.CA8063DD@IEEE.org>
Source record: 167037

I'm going to put up an elevated radial 40m vertical and drove up to Texas Towers on Wednesday to get the necessary aluminum tubing. They have a program that calculates wind loading. To my amazement, my design would fail at the base at 44 mph.

So I got to thinking about how to strengthen the base and came up with the idea to run a fiberglas pipe inside the bottom section and then a water pipe inside the fiberglas pipe. Now I'm wondering what effect the grounded water pipe would have on the vertical.

I guess the question is: Does RF flow on the inside of aluminum tubing being used as a vertical element? Would the insulated grounded rod on the inside of the aluminum tubing have any effect?

It sounds like you'd have a fiberglass dielectric capacitor, that would be important to the degree that the aluminum tube has a different rf voltage than the copper tube inside.

No, it also screens out the electric field.

Bart then asks: "All of it or only a part?"

Normally, the Faraday shield is quite effective, but that means little without quantitification, and I have no numbers.

A Faraday shield is a picket fence. The number and spacing of the pickets obviously affects the electric field terminations and screening, but the gaps can be ever so fine and they will still prevent circulation of induction current, so there nis no real problem.

This has been entertaining, but I really have to get back to work.

Thanks for all the comments. I now have a good idea of what "dissipationless" resistance is -- a vague, philosophical concept to which a numerical value can't be assigned (except in obvious, trivial cases), and not a quantity that can be used for any sort of analytical analysis. I'll stick to the one definition of resistance that's served me and my colleagues so well, and leave it to others to sort out "disspative", "dissipationless", and "ringer" resistances from one another. As far as I'm concerned, any analysis requiring "dissipationless" resistance for support may as well invoke poltergeists too.

I plan on installing a permanent mount (NMO) in my car for an antenna and curious as to what type of coax cable is best for use in a car. It needs to fit under headliner/carpet/under moldings etc, but I want as low of loss cable as possible under most frequencies (VHF will be used mostly). I could buy a mount with coax already attached but I don't know if, 1) the coax is high quality and 2) if the included cable is long enough.

I believe we would call this arrangement a "coaxial capacitor."

I think that you would have more strength at lower cost, if you used aluminum
for increasing the wall thickness of the bottom of the vertical. This doesn't
solve the insulation problem however.

>what you see in the short section of 50 ohm line.

That's where you are missing my point Steve. You keep clinging to the
idea the meter "looks like" a certain Zo line. It does, but the Zo a
typical lumped component dorectional coupler "looks like" has little
or nothing to do with the impedance it is set for.

It is a current transformer in series with the line, that looks like
very low series resistance with negligable inductance. It is a divider
across the line, that looks like a very high impedance.

Neither of those values are selected to "look like" anything in
particular.

I can take a 50 ohm meter, and with no change but a simple adjust,
make it a 25 meter or a 100 ohm meter. The impedance looking through
the meter won't change any measureable amount.

>50 ohm wattmeter indicates reflected power.

No, that's why the meter offers a nearly perfect impedance on bands
where the line inside the meter is a few degrees long. The directivity
comes from the temination in the slug, not the line section.

I can make a Bird meter, by adjusting a resistor inside the slug,
measure 75 ohm lines just fine. Of course on VHF and higher it would
start to put a "lump" in the 75 ohm line because the meter has extra
lead length outside the area where the sampling takes place. But at
lower frequencies, the Zo of the line section has nothing to do with
the null impedance of the directional coupler. We can make the null

impedance anything we want within reason.

The more common-lumped component meter is generally designed so the shunt impedance is many times the line Zo, and the series impedance many times less. The surge impedance of the meter has nothing to do with the null setting of the direction coupler section.

Wide-range RF bridges work this way, by varing one or two elements in the sampling section. You don't have to change the meter's Zo to change the null impedance.

Now at microwave, or even at UHF, things are a bit different because generally the line sections are long enough to have an affect. In that case you want them close to the line Zo, so they don't cause a mismatch.

>> No, it does not. It indicates a higher power because the voltage
>> divider has more voltage. It is a simple circuit that sums voltages
>> provided by current through the line and voltages across the line.
>>
>
>Yes it does. Transmission theory and the behavior of traveling waves does
>not change because the line is short.

This is not a line section type of sampling unit. It does not sample voltages or currents at two isolated areas spaced a large fractuion of a wavelength apart.

Its impedance does not matter much, the only thing that matters is the null adjustement for a give line volatge an line current when current and volatge are in phase.

>The voltage divider has more voltage because of the impedance
>discontinuities created by the 450 / 50 / 450 ohm mismatch.

Nope, doesn't have to do that. This does not have to be a fractional wavelength sampling section, it can be a lumped device....and almost always is at lower VHF, HF and lower.

>Your describing how the circuit works. You need to consider why the
>voltages and currents are changing.

That's right. I am describing how the sampling circuit works. It is a simple device that compares through current to across voltage, and sums the sampled voltages directly before rectification.

I can design them all day and all night without giving a "hoot" about the impedance of the sampling section. All that is necessary is the current transformer look like a very low Z, and the volatge divider look like a very high Z to the line....and the voltages from each be exactly equal when the I and E on the line are in-phase (or exactly out-of-phase) are in the correct ratio for the line Zo.

None of this requires the surge impedance of the sampling sections to equal the line Zo.

That's right. I am thinking about the most common type of directional
coupler used at low VHF and lower. Even a Bird behaves this way below
upper VHF.

You can get inside the slug and set the null for any line Zo you like,
without changing the line section impedance.

The Zo of the meter has nothing to do with detecting the forward and
reverse power. At upper VHF and higher, other methods are more
popular.

Tom:

At any point along a transmission line at any particular frequency one can measure a voltage V and a current I. This is completely unambiguous, however it is but one "view" of the transmission line. The view seen by a voltmeter and an ammeter. Other instruments and metrolgy will view it differently.

You can only measure one voltage across the line at one point at one frequency. Call it V.

Then if you wished to do so, you can resolve V (or I) into components in any way you might wish. It's arbitrary...

Its' sort of like finding the "components" of the number 42.

42 is the answer as you know!

And 42 can be resolved in an infinite number of ways...

For example 42 = 40 + 2, or 42 = 35 + 7 or, 42 = 35 + 10 -3, or 42 = 6 x 7 or... etc... How many ways can you express 42? An infinite number of ways. How many ways can you analyze and express the V and I at a point on a transmission line? An infinite number of ways, all of them valid and completely quantitative. [No dissipationless resistances here!]

Another way of looking at this is to look at a 2D circle in three dimensions. Sometimes it looks like an oval, sometimes it even looks like a line, but...it's still a circle according to one view. Or looking at a skeleton cube in two dimensions. Asking which of these views is valid is not really a proper question, they are all valid! Similarily there are many valid views of the voltage and current at a point on a transmission line.

What you are doing when you "observe" the voltage V and current I on a transmission line through a sampling directional coupler is to resolve V and I into sums according to a certain prescribed algorithm (view). Think of this as a computation done by a simple analog computer called incidently a directional coupler. If the coupler's sampling impedance is high enough [i.e. it's a very good directional coupler and it's insertion into the line does not affect the signals on the line, like the action of a high impedance voltmeter.] the signals V or I on the line will not even change or notice the insertion of the directional coupler. And the coupler will compute according to it's prescribed algorithm, or circuit design.

This algorithm, in most cases for ham directional couplers, used to "resolve" waves is simply:

Vr = V -IZo and Vi = V + IZo where:

Vr is the "so called" reflected voltage and Vi is the so called incident voltage. Change Zo then Vr and Vi change, but V and I are still the same "reality".

In terms of linear transformations what the directional coupler does is to rotate the vector [V, I] by means of a linear transformation based upon Zo into a new vector [Vr, Vi]. It's the same vector... just viewed from another angle...

In matrix format this rotation looks like (Reflected Wave, Incident Wave) = Transformation x (Voltage, Current) or...

```
Vr| = | 1 -Zo| |V|
Vi| | 1 Zo| |I |
```

So this question of the significance of waves revolves around the "significance" of Zo to some perceived or assumed "reality". The reference impedance of the directional coupler and the linear transformation it makes in the vector space of [V, I] is arbitrarily related to the meter/coupler not to the transmission line.

This is the basis of the "Generalized Scattering Formalism" wherein one can express or measure voltages and currents in terms of a set of arbitrary impedances. They don't even have to be real, they can be imaginary or complex or even functions.

If the reference impedance of the directional coupler Zo happens to be exactly equal to the surge impedance of a transmission line then one can use the directional coupler to "resolve" V and I into incident and reflected waves that correspond to a particular physical view of that special transmission line which supports (the numerous non-unique) solutions to the partial differential wave equations governing the lines.

However since those solutions are not unique we are not guaranteed that our view is the "real" one. And who cares? This view is no more or less valid than any other view, and one can easily perform all the quantitative scientific and engineering analysis and design one cares to perform to find other values of V and I anywhere on the system from any such view. Using any particular Zo as the basis for the view is no different or any less quantitative than using any other finite non-zero reference impedance. The oval is still the circle!

If you give me a directional wattmeter with any old reference impedance Zo, as long as I know its' Zo precisely, then I can use it to make measurements in any system of any other impedance or even of a non-constant impedance (wrt frequency) and I can use those measurments and results to calculate or design and predict quantitatively any other derivable quantities be they arbitrary waves or actual currents and voltages.

Now what is the appropriate Zo to use in a directional coupler for a line whose "surge impedance" varies over several orders of magnitude in both real part and imaginary part (surge resistance and surge reactance) within the band of interest? This is the "broad band" directional coupler problem! And... does it really matter? It all has to do with observability and

controllabilty. As long as observability is maintained under any assumed reference impedance then go ahead and measure those arbitrary waves with confidence, you can accomplish anything you need to do with those arbitrary views.

Now I assert that many hams using VSWR meters, especially those like me, who use them connected into unknown characteristic impedance lines connected to unknown impedance antennas to indicate when our "tuners" have satisfied the 50 Ohm requirements of our transmitter PA's, are measuring completely arbitrary "waves" which have no real physical significance to any particular model of the world. The meter indicates nothing about the actual waves on the system at all.

That's why I assert that "waves are arbitrary and non-unique" and depend only upon the metrology used to analyze and view them.

There may be some particular cases where a Zo in a sampling directional coupler corresponds exactly to some laboratory transmission line set up and thus measures a Vr and Vi that can be "seen" or expressed in another way that makes the observer feel warm and fuzzy about his particular view of reality, but... who the heck cares?

I explained that one.

The transmatch can be considered to look like three things, in any
combination:

1.) a Transmission line of some electrical length and impedance

2.) A transformer

3.) A shunt or series reactance of any sign.

>100 Watts / 1.22 Power Loss Factor = 81.97 watts seen at the antenna feed

Unless I'm missing something you did not consider the extra loss
caused by SWR on the feedline, which is pretty complex when the line
is short since losses are not distributed evenly between dielectric
and conductor losses.

Transresistance is nothing more than a constant of proportionality
between the input current and the output voltage. It just
happens to have the units of ohms which accounts for the "resistance"
part of the name. The people who thought up network theory were
fond of these little confusions. Nobody could ever mistake a
current-controlled amplifier with a resistor could he? Well?

Source record: 167058

Not sure what the C value was. I used the same L setting on 80 meters
as I use on a dipole that is resonate around 3850. The dipole has
almost no SWR in the shack on that frequency (fed with 100 feet of
rg-8x) (only about 20 feet up as I like to work a couple of friends
about 100 miles away and getting more height is difficult for me for
that antenna).

On 20 and 10 meters I set the capacitors almost full value and set the
coil switch to the lowest swr via the mfj meter, then adjusted the C for
the lowest swr on the mfj meter. I found I could get more power out
into the dummy load if I adjusted the MFJ for max power on the wattmeter
on the output side but could not be sure if that was because the input
power was changing or not. I could see the wattmeter on the input side
change, but did not take time to determin if the total out of the Icom
was changing or not.

I was just looking to see how much power was lost in the MFJ going into
a 50 ohm load and was hoping that the efficency does not change much
from that as I hook up some antennas.

You might not have measured the lowest loss possible on 80, since that
would be with maximum possible C that allows matching the load.

When a network has loss, maximum power transfer occurs with a little
mismatch. So the result you have where a slight mismatch raises load
power might be from that. It also could be from the transmitter not
"favoring" a perfect 50 ohm load. Most transmitters are like that.

Source record: 167066

I have an MFJ 40-15 loop in the attic of my condo townhouse. It's fairly worthless on 40m but will get out on the higher bands. I originally wanted to buy the 30-10m version. But after four months of backorder, at that time, I settled on the only unit MFJ, HRO or AES had in stock anywhere in the US. Using the loop indoors is frustrating if you're used to decent outdoor wire, verticals, etc. The worst aspect is the High Q. Bandwidth is extremely narrow so you end up retuning every few KHz. You pretty much have to be the one calling CQ. By the time you get the thing tuned someone else has answered or the calling station has gone away. The antenna is better than not operating at all but absolutely anything outside will be better. After 2 1/2 years of this agony I am looking for another solution. BTW, you can be successful on PSK31 since it's low power and many stations are concurrently working in the same SSB bandwidth. As for phone....

Tom, W8JI wrote:
"That transformer action is how the "shielded" loop transfers energy from the shield to the center."

The center is the loop coil which Tom imagines is his secondary and the shield over the loop is his imagined primary.

Problem is that the shield is broken in the middle with an insulator so that no current can flow around the shield. Fact is: No primary current, no secondary current. Tom`s scenario can`t possibly work.

There is no current flowing around the shield, which, were it to flow, would by Lenz`s law have to oppose the field which induces it in the first place. The imposed and induced fields would then be nearly equal and opposite and cancel each other leaving nothing for the inner loop.

This is what Tom correctly says happens when the gap in the conductive shield is shorted. No signal gets into the loop. This is the same as, for example, a loop of coax. When the shield is intact and conducts from end-to-end, the coax is effective in keeping r-f inside or outside the coax shield. If the coax shield is broken, the shield is no longer effective in keeping signals and noise in or out. Why does coax with a broken shield no longer keep r-f in or out? Because no current can flow through the shield. No counter field can be generated to cancel the magnetic component of the incident r-f. The incident r-f is free to induce signals as if the shield weren`t there. Not so with the electric field component of the r-f field. That time-varying electrictic flux alights on the shield and with proper balance in the grounding of the shield has no effect on the other side of the shield.

The broken shield action is how the Faraday shield works. It is effective in shielding the electric field while allowing excellent coupling of the magnetic field. This doesn`t offend J.C. Maxwell at all. The magnetic field penetrating the shield immediately generates a new electric field on the other side of the Faraday shield.

All of this has been known for about a century. It is taught in standard curricula. Why don`t you believe it?

Best regards, Richard Harrison, KB5WZI

Hi Ken, from what I read on newsgroups, published tests, fellow hams that own the antennas, and personal experience working these antennas on the air, these are my observations:
R8, OK performance on 40 and 30, best of the group on 20 and 15 on up.
Gap Titan, poor on 80m, OK on 40 - 30m , good on 20, 17 very good , fair on 10m.
MFJ 1798, Fragile construction (easily wind damaged), fair on 80 and 40, close to the R8 on 20, good on 15 and up.

Hope this helps...

6397. Antenna suggestions for Icom 706MKG

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-31 04:48:10 UTC
From: John Reed <jreed@NOSPAM.thor.atl.ga.us>
Message-ID: <tcao4u5bi54iad@corp.supernews.com>
Source record: 167068

HI folks:

I bought an Icom 706 Mk2G back in Janurary and I have been contemplating my antenna configuration.

Currently, I'm like this:

Comet SBB-5 2m/440 antenna coming out the VHF/UHF port on the 706MK2G
Larson 6m on the HF port.
(I'm buying a Screwdriver Antenna from Jerry Oxendine very soon)

I was originally planning on dropping a duplexer on the HF port so that I could run the Screwdriver on 10-80 and have a dedicated, resonant antenna on 6m.

Here's what I'm thinking about now:

I currently have the VHF/UHF antennas on MagMounts - and I hope to drill holes, soon. There's also a 220Mhz antenna up on the roof as well, so currently, that'd be 3 holes.

My idea was to put in a Comet 6/2/440 antenna (one hole to drill) and have another hole for the NMO 220 antenna. Since I'm putting the Screwdriver into the mix, it looks like I'm going to need 2 duplexers:

A duplexer to split out the 6m from the 2m/440 port.
A second duplexer to split out 6m from the HF port.

My question to the group is what are you doing with your 706MK2G? Jerry tells me that the Screwdriver antenna will show resonance on 6m if I stretch it out somewhere in the 7mhz area. Although I don't disagree with him, wouldn't an antenna cut for 6m be better?

Also, since I have 2 duplexers in the mix there, is that going to screw things up?

Thanks in advance!

John, N4TII

It is certainly related to the joules/second (power) measured at
a point. If power exists, it must be supported by a resistance,
i.e. at least part of the voltage and current must be in phase.
If the power measured at two different points in the same energy
pipe is the same, then the resistance at the first point must
be dissipationless.

> for increasing the wall thickness of the bottom of the vertical.

I already have the fiberglas and I don't have the aluminum. :-) In
fact, I chose the size of the bottom tube to fit snugly over the
fiberglas pipe.

Last time I used a wooden dowel to strengthen the fiberglas pole
but the wood got wet, swelled up, and split the pole. I assume
I can decrease the capacitance effect by insulating the six foot
water pipe from ground.

Source record: 166974

I've seen some European loops with some wide coverage's. The catch is this, a 10-80m loop's natural frequency is 10m. Here it is 95% efficient or better, but as you tune it lower this changes dramatically, by the time you tuned it down to 80 (you would need a killer capacitor) it's efficiency would be like 3% or less. The best way to go (loop wise) would having at least two loops, one for 10-30m another for 30 or 40-80m.

if you purchase the mount new from Larson, it will come with 18
feet of RG-58 already attached. been using them for over 15
years on 100 watt commercial radios. They work with no problems.

One hint on installing it. Put some silicon grease on the screw
threads. Makes it go together easy. When it comes time to
remove it several years down the road, it will come apart. No
lubrication, have fun trying to remove it. Have even used some
"Never Seize" (TM) when I didn't have any silicon with me.

Jim.

It will be a real mess. Looks like a big capacitor to ground.

How about guying the thing? Or using thickwalled fiberglass tubing for the base
insulator?
>
>I guess the question is: Does RF flow on the inside of aluminum
>tubing being used as a vertical element?

Normally, no - but putting that grounded pipe inside will change the current
distribution markedly.

>Would the insulated
>grounded rod on the inside of the aluminum tubing have any
>effect?

Sure - particularly if the capacitive reactance of the capacitor formed is low
enough.

Let's do the math. Assume a coaxial capacitor with an effective diameter of
1.27 inches. Its area is about 4 square inches per inch of length. Say you have
two feet of this - the area is 96 square inches. If the dielectric thickness is
1/4 inch, the capacitance is:

C = .224 x Area/spacing = 86 pF for air dielectric.

I don't know the dielectric constant of the fiberglass you want to use, but
it's at least 2 or 3, so you wind up with about 200 pF of capacitance across
the feedpoint of the vertical. If you use bigger tubing or a longer overlap it
just gets worse. 2-1/2 inch tubing and a three foot overlap with 1/4 inch
insulation gives about 250 pF with air insulation!

Good luck with it. What size tubing and what lengths are you considering?

Already bought it, Jim. The largest is 1.25" ID to slip over a
fiberglas pole that I already have. I've got six 6ft sections in
decending diameters. I was going to go with three 12ft sections
but the six sections were cheaper with less wind load.

> It will be a real mess. Looks like a big capacitor to ground.

Which means that there is RF on the inside of the tubing. Where do
the photons go?

> How about guying the thing? Or using thickwalled fiberglass tubing for the base
> insulator?

I've decided to do both. One of the three upper guys will be my 80m dipole.

Mike,
I have been using a "Larsen" glass-mount antenna for
approximately 5 years now. I have removed it from and re-installed it on 5
different vehicles. The only problem I ever encountered was the interference
caused by a malfunctioning rear-window defroster on one of those vehicles.
Aside from that one minor problem the antenna has performed flawlessly. I
highly recommend it for your application.

Hi Richard,

I presume by these picket fence pickets, you are speaking of the standard representation of fields graphically. This visualization technique is found widely in waveguide literature where the scale can bring examples into the lab or schoolroom.

However, at the other end of the spectrum I have encountered these pickets, literally. I have calibrated precision DC bridges that when you looked at the connections inside, you would swear at the lousy wiring and solder job. You would find half inch wire spikes tack soldered around the circuitry for no obvious reason (merely confirming the impression of sloppiness). However, as rude as it appears, these were calibrations applied to the bridge to allow it to measure another decade deeper into the null. The tacked on wires were used to balance the geometry of the fields that were upset by the choice of component placement (which is guaranteed to occur no matter what choice you make).

This balance of fields was part and parcel to calibration of capacitors and inductors too. And for the Faraday shield (you were at a loss for a number) we applied that technique to the isolation of windings in a transformer and could achieve winding-to-winding capacitance of less that 0.01 picoFarad. In Metrology, we employed variable transformers that span many (dozen) decades of

voltage/current range. The stray coupling of input to output has to
be strictly controlled and some times 0.01 pF is not enough separation
- even at low source/load Z's of 50 to 600 Ohms.

Your mileage may vary.

>
>Best regards, Richard Harrison, KB5WZI

Hi Richard,

The common mode is a current loop (distinct from the current loop of the primary circuit, and the current loop of the secondary circuit) that shares the same reference from input to output (hence the meaning of "common" and nearly always what we consider to be ground). Your example above solves many problems...

1. the primary loop, already mentioned;
2. the secondary loop, ditto;
3. from the ground, up through the generator, to the hot side of primary coil, through capacitance, to hot side of secondary coil, to load, to ground.

Insertion of the Faraday Shield upsets only one of these current loops. That one is the common mode loop. The Shield neither reduces nor negates the existing capacitance (it remains unchanged), it presents a new circuit. That is, there is a new path for current, and that former hot-to-hot coupling seeks ground through the shield instead of the load.

>Problem is that the shield is broken in the middle with an insulator so
>that no current can flow around the shield. Fact is: No primary current,
>no secondary current. Tom`s scenario can`t possibly work.

It will work perfectly well. The reason it works is we are talking
about impedances in a coupled circuit.

If I have a transformer with an open seconday the impedance across
that secondary, with the primary resonanted, will be very high. The
only way to make the secondary a low impedance, like that of the wire
itself, would be to remove it fromthe transformer so mutual coupling
has no effect.

>There is no current flowing around the shield, which, were it to flow,
>would by Lenz`s law have to oppose the field which induces it in the
>first place.

If there is no current flowing around the shield, you are in trouble.
The antenna can not possibly receive a signal. It will be stone dead.

Imagine taking a clamp-on meter and clamping it over the shield wile
the loop is excited with RF from a transmitter connected to the inner
conductor in a normal manner. We will read current in the shield. If
we take a voltmeter and tap it across a section of the shield, we will
read voltage.

If we measure voltage across the gap, it will be just as high as if we
feed the shield directly. Nothing changes except system balance.

>The imposed and induced fields would then be nearly equal
>and opposite and cancel each other leaving nothing for the inner loop.

Nope. Just the opposite happens.

The center of the loop is driven by current flowing on the inside
wall. We can consider that current to be driven by the voltage across

the gap in the loop.

If we take the voltage outside the loop to zero, as you say it does, all current flow inside the loop stops. We can do that by closing the gap with a short.

This is where you go wrong:

>broken shield no longer keep r-f in or out? Because no current can flow
>through the shield. No counter field can be generated to cancel the
>magnetic component of the incident r-f. The incident r-f is free to

There are enough silly arguments here Cecil, to the point where when
trying to make a point anyone trying to learn something is probably
totally confused.

If the load is 50 ohms resistive, you don't NEED a tuner. The
pi-network is NOT a pi-network when matching 50 ohms to 50 ohms unless
it has reactances of less than 50 ohms, which would be a very big
capacitor.

My statement is correct, a pi-network tuner is a very poor system for
matching wide-impedance range and frequency range loads because of the
very awkward component values required. It has an especially bad time
with low impedances on low bands, requiring thousands of pF of
capacitance. When you do that, you can't cover ten meters well if at
all....or high voltages that come with high impedances.

So my guess was pretty good. If you have 1/4 inch thick fiberglass, and we
assume the fiberglass has a dielectric constant of 4, you'll wind up with about
15 pF for every inch of overlap. Two feet works out to 360 pF or so. How thick
is the fiberglass, and how much overlap would you use?

Is the concern is that the fiberglass will fail or the aluminum will fail? I
presume the fiberglass, because it's at the point of highest stress.

> I've got six 6ft sections in
>decending diameters. I was going to go with three 12ft sections
>but the six sections were cheaper with less wind load.

You probably have just enough tubing for 1/4 wave resonance. If you overlap
each joint by six inches, the resultant antenna length is 36 feet minus 30
inches (five joints in six pieces) or 33 feet, 6 inches. The taper raises the
resonant frequency.
>
>> It will be a real mess. Looks like a big capacitor to ground.
>
>Which means that there is RF on the inside of the tubing.

Yup. Skin effect makes the RF current travel on the outside of the conductor.

>Where do
>the photons go?

They circulate in the reactance of the coaxial capacitor formed by the inside
of the tubing and the outside of the water pipe. They're not radiated.

Works for me. How many radials?

I've had good luck with EMT for verticals. Yes, the conductivity is far less, but at reasonable diameters the difference is negligible. Lots cheaper, but the joints are a pain.

Please pay attention, Tom. He made his test measurements using a
50 ohm dummy load. That was the context. Here's what he said:

"Easy to verify, load the rig to dummy load, put external wattmeter
between the rig and the dummy and switch your tuner in and out, you
will see about 20 % drop, like instead of 100W you will get 80 watts."

I responded to that statement. The context was a 50 ohm dummy load.

> My statement is correct, ...

So is mine and mine is even relevant to the contextual system
test configuration to which I was responding. :-)

Hey all, a really green newbie has a question.

I'm putting up a wire antenna on my roof, anchored in the center by my former TV aerial mast. The question on the table is: Assuming I have equal lengths on either side of the center point, is there any need for a balun? Elmer gave me one, and for some odd reason I feel obligated to use it. Do I need it or no?

Also, is there any reason I can't have a couple-three different lengths of wire coming off the center point? Or is this a situation where a balun might be useful?

Pardon my ignorance,
Eric Ruuska

> How thick is the fiberglass, and how much overlap would you use?

The fiberglas is 1/8" thick, 1 1/4" OD. The fiberglas pole on the other
end of my dipole broke and I use about 4.5' of overlap there.

> Is the concern is that the fiberglass will fail or the aluminum will fail? I
> presume the fiberglass, because it's at the point of highest stress.

Yep, my other fiberglas pole broke at the U-bolt. Due to the location
of my fence posts, the guys were not 120 degrees apart leaving me with
an undetected bistable condition. A big wind bent the fiberglas pole
into the undesired stable condition and the pole broke a few hours
later.

> Skin effect makes the RF current travel on the outside of the conductor.

The outside of the conductor on the inside of the tubing? Does that happen
if the water pipe is not inside the aluminum tubing? Is the current on
the inside of the tubing equal to the current on the outside of the tubing?

> >Where do the photons go?
>
> They circulate in the reactance of the coaxial capacitor formed by the inside
> of the tubing and the outside of the water pipe. They're not radiated.

Are electrons or photons circulating in that reactance?
Wouldn't photon circulation technically be called radiation?

> How many radials?

I'm going to start with four and make field strength measurements with
the radials laying on the ground and at 5' height intervals up to a
height of 25'. I suspect the field strength will be greatest with the
radials at 25'. I will then add four more radials and take the field
strength readings. I'll probably turn the results into a short article
for Worldradio magazine.

It is good engineering practice to use a balun at a balanced to unbalanced
junction. A center-fed dipole is balanced. Coax is unbalanced. Not all
hams follow good engineering practice.

Message-ID: <9a4r5dhhi1@nntp9.atl.mindspring.net>
Source record: 166997

What is the ID of the aluminum tubing you are using? I have several rejected base insulators for the CTSVR that could possible be cut down for your use. The insulator is UV resistant blue PVC 15" long, 1.75" OD, and turned down to 1.685" OD for a steel mast to slip over. 73, Ed - N5NUG

6425. QST-QST-QST--INVITATION TO THREE ANTENNA-RELATED REFLECTORS (LISTS)

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-31 14:59:26 UTC
From: fractenna@aol.com
Message-ID: <20010331095926.08237.00001869@ng-mn1.aol.com>
Source record: 166998

QST--

You are invited to join one or all of the following lists on yahoo groups(formerly
e-groups). All these reflectors are e-mail based, friendly, objective, and moderated ,so that no spam, porn, off-topic, or personal-offensive posts are sent out. Membership is screened against those with a history of disrupting/trolling. You will receive no off-list e-mails by subscribing: again; no spam.

Occassionally free offers of antenna files and other info are presented, along with photos of relevant antennas (unlike most NG's you CAN do attachments).

These lists (with some recent subscriber sizes) are:
ANTENNAS@YAHOOROUPS.COM 220 members
CROSSFIELDANTENNA@YAHOOGROUPS.COM 70 members
FRACTALANTENNA@YAHOOGROUPS.COM 310 members

Please review the descriptions at:

http://www.yahoogroups.com

Note the CFA list specifically deals with this antenna in an objectively critical fashion and no posts will be allowed that make grandiose claims without supporting data presented. To date, no data has been presented which requires the extraordinary claims made by some pundits: there is no evidence for better performance than any other small vertical antenna (and that performance is poor).

Fractal antenna posts should go the the fractal antenna reflector; not the antennas reflector. Note that Dr. Cohen, N1IR, the founder of fractal element antenna technology, uses this forum to answer questions on the web--exclusively. If you have a web-based question for him, kindly post it on the FAR assuming it is of general interest.

To subscribe to any list, either go through the process at egroups, or to skip the process (and some say 'annoying questions') just do:

---------- -subscribe@yahoogroups.com
where the ---------- is the name of a given list (such as 'fractalantenna')

Kindly do not query this e-mail address; the info here is complete for your information pleasure.

73,
Phil de

Source record: 167007

Bart, WB6HQK wrote:
"The statement that time varying fields can NOT pass through a conductor several skin depths thick is CORRECT.

Yes, if the conductor is extensive and unbroken.

I will repeat Terman`s 1955 comments.

Aluminum having low electrical resistivity is a practical shield for magnetic flux at radio frequencies.

"Magnetic flux in attempting to pass through such a shield induces voltages in the shield which give rise to eddy currents. These eddy currents oppose the action of the flux, and in large measure prevent its penetration through the shield."

"---Joints which interfere with eddy currents by adding resistance to the eddy current paths greatly reduce the effectiveness of a conducting shield". (Try insulators and see what happens.)

"---However, fairly effective electrostatic shielding can be obtained by a metal mesh made of any good to fair electrical conductor, which would be a rather poor shield for magnetic flux."

"It is possible to shield electrostatic flux without simultaneously affecting the magnetic field by surrounding the space to be shielded with a conducting cage that is made in such a way as to provide no low resistance path for flow of eddy currents, while at the same time offering a metallic terminal upon which electrostatic lines can terminate." (A Faraday shield)

Tom, W8JI is dead wrong that the electric field and magnetic fields are "INSEPARABLE". The Faraday shield was devised for exactly the purpose of separating the magnetic field from the electrostatic field in a "time-varying" EM wave.

Tom`s declaration that the Faraday shield is just the plate of a capacitor is laughable.

Best regards, Richard Harrison, KB5WZI

6428. CQ Magazine-3dB gain HF mobile antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-31 15:14:30 UTC
From: 2w8ji@akorn.net
Message-ID: <3ac5ef27.61501563@news.accessunited.com>
Source record: 166999

The latest issue of CQ contains an interesting tidbit of information.

On page 61, the author states "A number of readers have urged me to discusss the concept of phasing two mobile antennas for big signal mobiling...."

I'll bet they have!!!

The author goes on to say if you run two HF mobile antennas on your car, one on each side of the trunk and feed them in parallel, you gain 3dB!!!!! Now he admits "wider whip spacing is preferable for 40 and 80 meters"...but he goes on to say the 3 dB does appear on 30 meters and above.

The author pontificates about cable length, advising people to stay away form pesky "resonant lengths like 1/4 wl or 1/2 wl" that cause problems.

He talks about how, when we space antennas 1/2wl apart, the gain is "4 or 5dB" but since we can't get that spacing a "trunk width is good for 3dB".

In other articles by the same author, I learned the radiaton in a mobile antenna all comes from the area ABOVE the loading coil. I learned about power amplifiers, and how they work. One thing....these articles are dependable. They are all of the same educational quality and accuracy.

I did write him once, and he wrote back saying I was the only one who thought his articles contained errors.

Hi Tom:

You're talking about adjusting the sampling or measuring circuit to indicate power as if it were a 25 ohm or a 100 ohm meter. I agree that the impedance in the meter does not change. As a result, the voltages and currents that are measured do not change either. You have just changed the circuit to indicate different power levels.

That's like me saying take the slug out, no power is indicated on the meter, therefore the power must be zero. I agree that you can adjust the circuit to indicate just about any power level. This does not change what is

physically happening in the transmission line section of the meter.

> >> A well-designed meter looks like nothing at all to the line. The Zo

>

You're talking about the directivity function in the measuring circuit. Again, you're discussing how the bird circuit works, not what's happening in the transmision line section of the meter.

In the example you describe, the output connector of the bird meter effectively "sees" a 450 ohm "termination". A rearward traveling reflected wave is created at this termination. This rearward wave does not travel rearward beyond the bird input because of the 450 / 50 ohm discontinuity seen in the rearward direction (assuming a 450 ohm transmitter output impedance).

The level of reflected wave traveling in the 450 ohm line in front of the bird meter is a direct function of the impedance seen looking rearward into the 450 ohm line from the meter input. Let's assume that the transmitter output impedance is not 450 ohms. If you adjust the length of the 450 ohm line such that this rearward impedance becomes 50 ohms (or some other low 50 ohm SWR value), a rearward wave will now travel in the 450 ohm line. When the transmitter output impedance is not 450 ohms, the location of the 50 ohm bird meter will impact the level of forward and rearward power traveling in the 450 ohm line in front of the meter.

This is why the 50 ohm meter indicates different forward and rearward powers as you move it along a 450 ohm line. The output termination it sees remains 450 ohms. The rearward impedance it sees changes, causing a different level of re-reflected power. Hence the forward and rearward power levels change.

Ken --

Had my Titan for 3 months. If the others are better, folks would have to hear you before you push the xmit switch. I think all of them are credible ants.

All of them have narrow bandwidth on 80 M. Just make sure that your expectations for 80 are reasonable. Also be aware that on ground wave QSOs, the vertical polarization will make a difference -- unless you're talking to another vertical.

All and all, the GAP is a great antenna -- but plan on guying it. It's solid, but unguyed, it's pretty spooky. Dacron string be cheaper than a new antenna.

I don't work for GAP or a distributor, and the suckers haven't offered to bribe me -- dang it.

Well, there is a tiny grain of truth there. 1/8WL on 28.4 MHz is
4.33ft. If we feed two 8.25ft whips 180deg apart, we can expect
close to 3dB gain over a single whip.

My pickup is just about 1/8WL long on 40m. Seems I could get
3dB gain on 40m with proper phasing of bumper mounted phased
verticals. 2dB sure would help at a 75m mobile shootout. :-)

On 17m with a rear bumper mounted screwdriver, I can gain an S-unit
(probably not 6dB) by pointing my truck in the direction of the
receiver. It is similar to a vertical with one very fat radial.

Richard Clark, KB7QHC wrote:
"Insertion of the Faraday Shield upsets only one of these current loops."

Yes, it upsets, in fact prevents, an induced current loop in the Faraday shield by slicing it up into little pieces.

The shield could be made from rows or columns of wires soldered to a copper plane. An insulated wire or wires could be routed between the ranks of wires.

In a forest of grounded wires, a conductor running through the forest would be susceptible to external magnetic fields, but not so susceptible to electrostatic fields. That is how a Faraday shield works.

Terman briefly describes the effects of coil proximity to shields, the addition of high permeability materials to improve magnetic shielding, and placements which might lead to pot-core construction. But, all of this is outside the function of a Faraday shield which works the same way in a 60-Hz transformer, broadcast transmitter antenna coupler, or a shielded loop, for the most part.

Electrostatic field shielding means the same thing as time-varying electric field shielding, and magnetic field shielding means the same thing as time-varying magnetic field shielding to the "Ancients" when they discuss the Faraday shield.

The Ancients were not discussing balancing bridge capacitance with strategically placed grounded wires when they were discussing shielded loops. That technique could well be beneficial as Richard Clark noted. But the basic function of the Faraday shield is to hold off the electric field and let the magnetic field couple into a loop or coil. This works!

The Faraday shield does benefit from capacitive balance to avoid error when it is being used as a direction finder, and this balance may be used to maximize electric field insensitivity.

Richard Clark gave a nice description of how insertion of a shield affects pre-existing capacitance and produces new capacitances. Pages more could be added, but wouldn`t necessarily help zero-in on the function of a Faraday shield.

Best regards, Richard Harrison, KB5WZI

A better antenna brings up all signals in the passband including
interference. There are directive antennas out there like the various
tunable loops which are useful in reducing intereference but the
selectivity of the radio is by far the most critical factor in
reducing intereference. Selectivity costs money, etc.

Ralph:

I think I mis-typed what I meant to say.

I'll need 2 duplexers....

One to split 6m off from the HF port.
One to COMBINE 6m with the 2m/440 signal to a single coax going to antenna.

See what I'm trying to do? I'm trying to figure out the best way to run a 6m/2m/440 antenna (like the one KK4TL is selling, but I'm going to get the shorter one), AND still be able to have the Screwdriver antenna.

(That leaves the single NMO up front, dead center on the roof, for my 220 antenna - only 2 holes to drill).

John

Hi Steve,

The technical name for this observation is Mismatch Uncertainty, and
is common where the Source Z, the Transmission Line Z, and the Load Z
are all different (or different in such a way as to present the
measuring device huge mismatches at both the input and output).

Most Lab nomographs indicate that a 2:1 mismatch at both terminals
will present erroneous power readings of ï¿½50% MINIMUM (whereas 1.15:1
mismatches merely present erroneous power readings of 5%). Mismatches
of 9:1 are literally off-the-chart.

6449. Sailboat Antenna options

Newsgroup: rec.radio.amateur.antenna
Date: 2001-03-31 17:33:38 UTC
From: Loose Lines Limited <looselines@lavac.com>
Message-ID: <wxox6.2261$e9.69013@news1.fdn.com>
Source record: 166923

We are moving aboard our boat and looking for an antenna system. Several options are available but only four are practical.

1. Insulated backstay.
Pros: Relatively easy to do and easy to hook up.
Cons: Relatively expensive as a rigger would have to add the insulators, fixed length of about 40 feet

2. Just hook up to standing rigging with no insulators (use whole rig)
Pros: Very easy to do, inexpensive
Cons: I have no idea the radiation pattern or reception capabilities but some have said no problems

3. Freestanding whip
Pros: Moderately easy to do
Cons: Relatively expensive to purchase and mount

4. Wire center fed dipole hoisted up when radio is in use
Pros: Inexpensive, very good transmission/reception characteristics
Cons: Damned awkward to keep hoisting and retreiving the thing.

Equipment is a new ICOM 718 (snipped) and a SGC 237 tuner.

By the way, the dipole has other advantages as the boat at present is not rigged for HF transmissions and an extensive ground will have to be installed for all the other antennas.

Environment is salt water cruising.

I would appreciate any input or thoughts on the matter. I am brand new to amateur radio and any assistance would be most welcome.

Tom

>effect?

Hi Cecil,

No.

BUT, as you describe grounded rod being INSIDE the radiator (not good at all) but elsewhere you specifically draw a gap between the radiator and the water pipe - you have muddied the waters.

You should be looking at the radials if you are worried about the water pipe. Add more radials if you get that worried about it. Or simply tie them to that same water pipe. ????

If you wish to pursue this logic of capacitance, your design best(worst) illustrates a split stator design. If your radials do not connect to the water pipe, but couple capacitively to it, that is one stator half. The water pipe INSIDE the radiator constitutes the other stator half. The metaphor of split stator design would have the water pipe as the rotator/plunger. Your design, as illustrated, shows the capacitor is fully meshed with one stator half and coupling to the radiator is accomplished only through stray capacitance (which is common to every design). It is instructive to note that this capacitance imbalance is beneficial - but a simple Ohmic connection would infinitely simpler and effective.

Your only problem:
Keep that water pipe from bridging your feedpoint.

: Best regards, Richard Harrison, KB5WZI

Richard,

I will assume that the wires of the cage are many skin depths thick.
While that is not true at 60Hz, this thread is about shielded loop
antennas. A skin depth in copper is .05 millimeters at 160 meters
(about .002 inches) so 12 gauge wire is about 20 skin depths thick at

that frequency. Let's imagine that during manufacturing a little air bubble was formed in the center of one of those wires. A microbe living in that bubble would see itself surrounded by solid copper many skin depths thick. I think we all agree that if we make a container of solid copper many skin depths thick, it shields the interior from both external electric and external magnetic fields. Saying that there is a magnetic field many skin depths inside the wire is equivalent to saying that filling the air bubble with copper suddenly makes a magnetic field appear.

Any point in the interior of a copper shield is obviously surrounded by copper, and this copper can be thought of as shorted turns. There is no problem with a current circulating around any point in the interior of the copper. It is exactly these currents that make the magnetic field in the interior go to zero exponentially with the number of skin depths, and the magnetic field does not penetrate deep into the copper. It does not require the copper to be large and extensive, a sphere of copper 1 millimeter in diameter at 1.8 MHz will have fields at its center about 40 dB down from those on the surface.

Hi Bill,

My own experience, and my reading of others here suggests that the
lowest band is not a very good performer (for any design). Each
succeedingly higher band did improve though. I can attest to it being
a very, physically, robust design. Mine elevated at a dozen feet or
so has withstood some gale force wind without resort to guying.
Tuning has remained dead-on for years.

When it comes to verticals, you can only hope you have the lowest loss
model (don't even think of gain) that matches to your rig easily.

Hi Richard,

In fact I said that the capacitance did not change and that a new
circuit had been added.

I was wrong, but not substantially. The addition of the physical
shield necessarily changes the geometry of the initial capacitance.
In some designs this could be substantial (like in a power
transformer) but in your specific example, it was unlikely to change
it markedly.

The new circuit places ground closer to the coils and must necessarily
change their characteristics - however, even here with the example
responded to, this is minimal.

As for:
>
>Yes, it upsets, in fact prevents, an induced current loop in the Faraday
>shield by slicing it up into little pieces.
>
sounds more like the operation of laminated core than Faraday shield.
Further, I presented only three current loops, one being the Common
Mode that you asked for. Within the context of the example responded
to, can you give the full path of this induced current you speak of
above?

[snip]

I agree with Tom.

I believe that you may be confusing the metrology of measuring waves with the characteristics of the transmission media itself. A reflected voltmeter or SWR "meter" needs no line section.

There are as many ways of measuring waves on transmission lines as there are engineers to invent them. Some SWR or reflected voltmeters do have line sections in their construction, but line sections are by no means necessary to the precise and accurate measurement of waves. Good traveling wave meters can be constructed without line sections.

A "sampling directional coupler", that is a device which can accurately and precisely measure reflected and incident wave voltages without disturbing the line, does not need a "section of line". In fact if well made, it can be completely transparent to and not perceptably disturb the line when inserted..

The only "circuitry" required to non-invasivly "tap" across and through a transmission line, or any kind of network for that matter, and accurately indicate incident and reflected voltages is a simple but high impedance bridge circuit to measure voltage and a simple low impedance current sampler.

A reflected voltmeter is nothing more nor less than a high impedance bridge combined with a low impedance current sampler. It has no need for an "intrinsic" characteristic impedance of its' own but needs to use a "facsimile" of Zol as a reference impedance with which to "compute" the reflected and incident voltages present on the line. In fact, although in practice it often does, the Zo of the metering device used to compute the

"waves" from the current and voltage, need have no relationship to the Zo of the line to be useful.

If V is the voltage across a line or network port at a certain point and I is the current in the line or network port at the same point, then one can sample V (with a very high impedance "across" probe) and sample I (with a very low impedance "through" probe) and then use one of several methods of calculating and displaying the "wave variables" A and B.

The desired wave variables A and B are nothing more nor less than a simple linear transformation of the line voltage V and current I. Where A is the incident wave and B is the reflected wave.

The computation required to transform V and I into A and B, be it performed in digital or analog circuitry is simply:

B = V - IZo "The reflected wave voltage with respect to Zo"
A = V + IZo "The incident wave voltage with respect to Zo"

The "metering" device itself, needs no "line section". In fact the so called line section in the meter can be "vanishingly small" and have no perceivable characteristic impedance itself.

All one has to do to measure the "waves" is to measure V and I and perform the above computation.

By simple algebra you can readily check that B = rho * A where rho is the reflection coefficient, [rho = (Z-Zo)/(Z+Zo)] calculated with respect to Zo if the line or network port beyond the meter has an impedance Z.

I see no need for a line section in such a metering device.

Rick:

So it seems that everyone on this thread is still ignoring the "elephant" in the corner of the thread. The one sitting over there in the imaginary corner. It is truly dissipationless. And no one has commented... why?

What about "imaginary resistance"?

Is Z = jR a valid concept? Indeed can Z = jR be physically constructed or at least approximated closely.

I maintain that devices whose voltage, current characterization is Z = jR = V/I can be approximated in reality as closely as desired.

I claim that one can build a device with impedance Z = jR where the voltage and current over any band of interest are 90 degrees out of phase but the impedance does not vary with frequency as with inductive and capacitive reactance. There will be a lot of parts in the black box used to build it, but... at least, unlike that other dissipationless resistance, it's real!

I assert that these somewhat arcane, but nevertheless real devices, the imaginary resistors jR, are in fact the ONLY real dissipationless resistances. This imaginary resistance is fully computable, measureable, and quantitative and requires no one to suspend beliefs and accept miraculous ideas.

And after all... it is a "resistance" without dissipation. That is no electrical energy or power is converted to heat within!

Comments, thoughts,

-Peter K1PO

I think it might be more illustrative to think of the shield and pickup loop each as separate secondaries on the same transformer. In a conventional power transformer, current in the primary generates a magnetic field which is shared by all secondaries. The terminal voltage (per turn) measured across any winding is identical because it is the same magnetic flux which links them all, at least for the ideal transformer. In the case of the receiving loop, the excitation is provided by an incident electromagnetic wave which can be considered to be a 'virtual primary winding'. The shield and pickup loop both encircle the same magnetic flux and will therefore have identical terminal voltages.

Suppose both shield and pickup loop are open circuited. The current flowing is negligible and no energy is transferred into, or out of either 'winding'.

> That transformer action is how the "shielded" loop transfers energy
> from the shield to the center.

There really is not transfer of energy from one winding to another. Both shield and pickup loop are coupled magnetically to the same region of space. Any energy in the magnetic field available to the shield is also available to the pickup loop.

> The shield, resonanted through mutual
> coupling to the resonant secondary inside, becomes the antenna.

I don't see how resonance has anything to do with it. The pickup loop and shield form a coaxial transmission line. In order for the loop to act as a receive antenna, some current must be allowed to flow around the loop. This current is common mode to the shield / pickup loop system and will actually flow on the outer surface of the shield since only differential mode currents exist 'inside'. This phenomenon could be interpreted as the shield being the antenna but I don't think it is an important concept.

> The
> field impedance of that antenna is very little different than the
> secondary winding alone would be without the shield.

Since the net current on the shield is zero, it has no significant
effect on the magnetic field except in the very near vicinity of the
conductors themselves. Presumably the area enclosed by the loop is
large compared to the cross section of the shield and the effect of the
shield is insignificant other than to establish the diameter of the loop
conductor, and thereby it's inductance.

> The only major difference is the amount of reactance to resonante the
> loop can change, and the balance can change.

This depends on where the break in the shield is located compared to the
pickup loop terminals. The most common configuration locates the break
in the shield is on the other side of the loop from the pickup
terminals. This results in a differential mode voltage appearing between
the shield and pickup loop. The inner conductor to shield capacitance
shunts this voltage and reduces the external capacitance required to
resonate the loop. This effect is nullified if the break in the shield
is at the same location as the break in the pickup loop. The later
configuration allows the loop to operate at a higher frequency but the
grounding of the shield is more complex.

> If you do NOT ground the
> shield in the electrical center of the shield it can actually hurt the
> system balance, and increase response to undesired electric fields.

That's for sure. Any unbalance will result in coupling between the
common mode electrostatic field the shield is supposed to suppress and
the differential, or 'circulating' mode which is desired.

Source record: 166936

I tried the experiment of using a capacitor on one of the radio's I've been using for the shield testing.
I used 6800 pF, which at 740 KHz actually is less than 50 ohms, from a ten-inch whip to the outside of the receiver coax antenna connector. The result is interesting.

Yes, it does attenuate the received signal, but not nearly as much as placing the radio and antenna inside
a conductive tube, or even close alongside a conducting object longer than the radio and its antenna.
This is probably due to the fact that the impedance of a small conductive object at RF is near ZERO
ohms, not the 50 ohms (or less ï¿½ I used a bigger cap than needed) of this experiment.

And there a couple of other things about this particular experiment that don't reproduce reality. One is, the receivers I use, and that most of us use, have low impedances themselves, which is one reason short probe antennas work so poorly when we use them. The other is, placing a 50 ohm capacitive reactance across a loop feedpoint -- a much smaller impedance than a receiver's 50 ohms - makes even less difference in power delivered to the receiver, meter or load on the loop than it would across a 50 ohm point. I have not in fact tried putting a capacitor across a loop's output -- but because it IS a low impedance, I would expect no great difference if I did so.

Cortland

Yes, I was also concerned that a radio having both a loopstick and a whip would confuse things. The AR8000 has an internal loopstick, and I took off the whip antenna. I could not use that receiver for electric-antenna (probe) comparisons because of the simultaneous presence of the loop. Other wideband handheld receivers have no internal loopsticks, however, and I do have some of those as well.

The signal decrease with a loop inside the conducting tube appears related to how close to the side of the tube the loop turns are; this is the shorted-turn effect I referred to. 7 inch diameter aluminum tube is what I could find. If I can find something larger, or use a smaller loop, I may be able to get a better feel for that effect.

>to use it. Do I need it or no?

NEED it? No. The antenna will work fine. But using coax, you may get currents on the feed line, which can cause TV interference, and a balun would go a long way to reduce/eliminate such currents. You could also use ferrite beads with the same effect. Using open line, ladderline or twin lead feeder (all are balanced lines) there's no need for a balun at the antenna, but you would need one at the tuner or radio.

A balun (short for balanced-unbalanced) provides a match between the coax's center lead and the braid. The output of your radio is designed to be unbalanced (it is a coax connection).

>Also, is there any reason I can't have a couple-three different lengths
>of wire coming off the center point?

Not a problem. But there will be some coupling between the wires, so the resonant lengths might be a little hard to determine. This is a good situation for an antenna analyzer. You may get results almost as good by simply using a single wire dipole, cut for resonance on some frequency, that can be matched with a tuner on other bands.

All that having been said, I have four coax fed dipoles, two with baluns, and two without. All work well. None are giving me any TVI problems (at the moment).

The more general case does not require resonance. What about the non-resonant condition? For that matter, what if I resonate a shielded loop at the feedpoint, instead of at the shield gap?

Kevin, W9CF wrote:
"Any point in the interior of a copper shield is obviously surrounded by copper, and this copper can be thought of as shorted turns."

Nice characterization!

Terman says:
Skin depth of copper in cm = 6.62 / sq.rt.F
Or, at 1 MHz = 0.0066 cm, or 0.0026 in.

So, skin depth is inversely proportional to the square root of the frequency.

Obviously sheets of copper a few thousandths of an inch thick don`t shield well at 50/60 Hz.

The power transformer`s electrostatic shield is not there to block the power frequency. It is there to block higher frequency trash. Transients are frequent on power mains and contain a broad spectrum of noise.

To block lower frequencies, permeable magnetic materials are added to the shield.

Best regards, Richard Harrison, KB5WZI

I beg to differ. Both my modelling and my experimental results show it's quite possible to get considerable gain using solid-poly dielectric cable. (The gain is practically the same for solid dielectric and foam dielectric cable if the overall antenna length is the same.) The three elements needed to be successful: get the elements radiating in phase (1/2 wave sections, accounting for velocity factor), match the feedpoint to the feedline, and thoroughly decouple the antenna from the feedline.

(Sorry that it's become very inconvenient for me to track postings, so it's unlikely I'll see replies posted to this...)

I actually like the design (technically speaking) of the Butternut
antennas but they require a radial set. I'm dealing with balcony
mounting here... :)

Know what, Zoran; I give up.

There are people who are thoughtless drones, no matter how hard you hit them with a hammer. Charles is one of them. He doesn't care about usenet and he doesn't care about other people's interest in this fabulous medium. He sees it as the perfect place to run his adv^H^H^HSPAM and think that it's just great.

He behaves like the simplex idiot who is too stupid to grasp the concept of split operating. In that vein he is unable to grasp the concept of a text based, ad-free and multicultural environment that has been designed to discuss ideas, not to promote ridiculously bad designed and contentless webpages. He laughs at people who think that his fullquotes, referenceless drivels are a waste of conceptual bandwidth.

Let him have it his way. Let him be happy in his dysfunctional way of not understanding what 2-way communication at its best can be. Let's leave him alone and pray for www.usenet2.org where mindless people like him will never have a place.
